Oracle PL/SQL Language Pocket Reference

Introduction

The *Oracle PL/SQL Language Pocket Reference* is a quick reference guide to the PL/SQL programming language, which provides procedural extensions to the SQL relational database language and a range of Oracle development tools. Where a package, program, or function is supported only for a particular version of the Oracle database (e.g., Oracle Database 11*g*), we indicate this in the text.

The purpose of this pocket reference is to help PL/SQL users find the syntax of specific language elements. It is not a self-contained user guide; basic knowledge of the PL/SQL programming language is assumed. For more information, see the following O'Reilly books:

Oracle PL/SQL Programming, Fourth Edition, by Steven Feuerstein with Bill Pribyl

Learning Oracle PL/SQL, by Bill Pribyl with Steven Feuerstein

Oracle PL/SQL Best Practices, Second Edition, by Steven Feuerstein

Oracle in a Nutshell, by Rick Greenwald and David C. Kreines

Acknowledgments

We are grateful to all those who helped in the preparation of this book. In particular, thanks to Bryn Llewellyn for his

input on this latest revision as well as the third edition. Thanks as well to first-edition reviewers Eric J. Givler and Stephen Nelson and to second- and third-edition reviewer Jonathan Gennick. In addition, we appreciate all the good work by the O'Reilly crew in editing and producing this book.

Conventions

UPPERCASE indicates PL/SQL keywords, as well as certain identifiers used by Oracle Corporation as built-in function and package names.

Italic indicates filenames and directories, as well as the first use of a term.

Constant width is used for code examples, literals, and identifiers.

Constant width bold indicates user input in examples showing an interaction.

[] enclose optional items in syntax descriptions.

{} enclose a list of items in syntax descriptions; you must choose one item from the list.

| separates bracketed list items in syntax descriptions.

PL/SQL Language Fundamentals

This section summarizes the fundamental components of the PL/SQL language: characters, identifiers, literals, delimiters, use of comments and pragmas, and construction of statements and blocks.

PL/SQL Character Set

The PL/SQL language is constructed from letters, digits, symbols, and whitespace, as defined in the following table:

Type	Characters
Letters	A–Z, a–z
Digits	0–9
Symbols	~!@#$%^&*( )_-+=|[ ]{ };"'<>,.?/ ^
Whitespace	space, tab, newline, carriage return

Characters are grouped together into four lexical units: identifiers, literals, delimiters, and comments.

Identifiers

Identifiers are names for PL/SQL objects such as constants, variables, exceptions, procedures, cursors, and reserved words. Identifiers have the following characteristics:

- Can be up to 30 characters in length
- Cannot include whitespace (space, tab, carriage return)
- Must start with a letter
- Can include a dollar sign ($), an underscore (_), and a pound sign (#)
- Are not case-sensitive

Using PL/SQL's reserved words as identifiers in your programs is not a good idea and can result in compilation or runtime errors that are difficult to troubleshoot.

TIP

Earlier editions of this book included a list of reserved words. However, Oracle Database 11*g* Release 1 has more than 1600 reserved words as listed in the V$RESERVED_WORDS data dictionary view. In our testing we determined that more than 650 of these could not be used as procedure names or variable names. Consult V$RESERVED_WORDS for the full list of unsupported identifiers, and avoid using these as program or variable names.

If you enclose an identifier within double quotes, all but the first of these rules are ignored. For example, the following declaration is valid:

```
DECLARE
   "1 ^abc"  VARCHAR2(100);
BEGIN
   IF "1 ^abc" IS NULL THEN ...
END;
```

Boolean, Numeric, and String Literals

Literals are specific values not represented by identifiers. For example, TRUE, 3.14159, 6.63E-34, 'Moby Dick', and NULL are all literals of type Boolean, number, or string. There are no complex datatype literals as their values are internal representations; complex types receive values through direct assignment or via constructors. Unlike the rest of PL/SQL, literals are case-sensitive. To embed single quotes within a string literal, place two single quotes next to each other.

Starting with Oracle Database 10*g*, you can define your own quoting mechanism for string literals in both your SQL and PL/SQL statements. Use the characters q' (q followed by a straight single quote) to designate the programmer-defined delimiter for your string literal. Terminate the literal string with the programmer-defined delimiter followed by a trailing single quote—for example, q'!my string!'. NCHAR and NVARCHAR delimiters are preceded by the letters nq, as in nq'^nchar string^'. This technique can simplify your code when consecutive single quotes appear within a string, such as the literals in a SQL statement. If you define your delimiter with one of the four bracketing characters ([{<, you must use the righthand version of the bracketing character as the closing delimiter. For example, q'[must be closed with]'.

See the following table for examples:

Literal	Actual value
'That''s Entertainment!'	That's Entertainment!
q'#That's Entertainment!#'	That's Entertainment!

Literal	Actual value
'"The Raven"'	"The Raven"
'TZ=''CDT6CST'''	TZ='CDT6CST'
q'$TZ='CDT6CST'$'	TZ='CDT6CST'
q'[TZ='CDT6CST']'	TZ='CDT6CST'
''''	'
'''hello world'''	'hello world'
q'!'hello world'!'	'hello world'
''''''	''
q'['']'	''
nq'<Price='£'>'	Price='£'
nq'-WHERE name LIKE 'ñ'-'	WHERE name LIKE 'ñ'

Numeric Literals

You may achieve improvements in runtime performance by making explicit the datatype of numeric literals. You can do so by including or excluding a decimal point or by using a trailing f or d, as shown in the following table:

Literal	Datatype
3.14159	NUMBER
42	INTEGER
0.0	NUMBER
3.14159f	BINARY_FLOAT
3.14159d	BINARY_DOUBLE

Oracle Database 10g introduced several special named constants:

    BINARY_FLOAT_NAN (Not a Number)
    BINARY_FLOAT_INFINITY
    BINARY_FLOAT_MAX_NORMAL
    BINARY_FLOAT_MIN_NORMAL

BINARY_FLOAT_MAX_SUBNORMAL
BINARY_FLOAT_MIN_SUBNORMAL

as well as the BINARY_DOUBLE versions of these constants.

Datetime Interval Literals

The datetime interval datatypes, introduced in Oracle9*i* Database, represent a chronological interval expressed in terms of either years and months or days, hours, minutes, seconds, and fractional seconds. Literals of these datatypes require the keyword INTERVAL followed by the literal and format string(s). The interval must go from a larger field to a smaller one, so YEAR TO MONTH is valid, but MONTH TO YEAR is not. See the following table for examples:

Literal	Actual value
`INTERVAL '1-3' YEAR TO MONTH`	1 year and 3 months later
`INTERVAL '125-11' YEAR(3) TO MONTH`	125 years and 11 months later
`INTERVAL '-18' MONTH`	18 months earlier
`INTERVAL '-48' HOUR`	48 hours earlier
`INTERVAL '7 23:15' DAY TO MINUTE`	7 days, 23 hours, 15 minutes later
`INTERVAL '1 12:30:10.2' DAY TO SECOND`	1 day, 12 hours, 30 minutes, 10. 2 seconds later
`INTERVAL '12:30:10.2' HOUR TO SECOND`	12 hours, 30 minutes, 10.2 seconds later

Delimiters

Delimiters are symbols with special meaning, such as := (assignment operator), || (concatenation operator), and ; (statement delimiter). The following table lists the PL/SQL delimiters:

Delimiter	Description
;	Terminator (for statements and declarations)
+	Addition operator

Delimiter	Description
-	Subtraction operator
*	Multiplication operator
/	Division operator
**	Exponentiation operator
||	Concatenation operator
:=	Assignment operator
=	Equality operator
<> and !=	Inequality operators
^= and ~=	Inequality operators
<	"Less-than" operator
<=	"Less-than or equal to" operator
>	"Greater-than" operator
>=	"Greater-than or equal to" operator
(and)	Expression or list delimiters
<< and >>	Label delimiters
,	(Comma) Item separator
'	(Single quote) Literal delimiter
q' and '	Programmer-defined string literal delimiter
nq' and '	Programmer-defined NCHAR string literal delimiter
"	(Double quote) Quoted literal delimiter
:	Host variable indicator
%	Attribute indicator
.	(Period) Component indicator (as in *record.field* or *package.element*)
@	Remote database indicator (database link)
=>	Association operator (named notation)
..	(Two periods) Range operator (used in the FOR loop)
--	Single-line comment indicator
/* and */	Multiline comment delimiters

Comments

Comments are sections of code that exist to aid readability. The compiler ignores them.

A single-line comment begins with a double hyphen (--) and ends with a new line. The compiler ignores all characters between the -- and the new line.

A multiline comment begins with slash asterisk (/*) and ends with asterisk slash (*/). The /* */ comment delimiters also can be used for a single-line comment. The following block demonstrates both kinds of comments:

```
DECLARE
    -- Two dashes comment out only the physical line.
    /* Everything is a comment until the compiler
       encounters the following symbol */
```

You cannot embed multiline comments within a multiline comment, so be careful during development if you comment out portions of code that include comments. The following code demonstrates this issue:

```
DECLARE
    /* Everything is a comment until the compiler
       /* This comment inside another WON'T work!*/
       encounters the following symbol. */

    /* Everything is a comment until the compiler
       -- This comment inside another WILL work!
       encounters the following symbol. */
```

Pragmas

The PRAGMA keyword is used to give instructions to the compiler. There are five types of pragmas in PL/SQL:

AUTONOMOUS_TRANSACTION

Tells the compiler that the function, procedure, top-level anonymous PL/SQL block, object method, or database trigger executes in its own transaction space. See the "Database Interaction" section for more information on this pragma.

EXCEPTION_INIT

Tells the compiler to associate the specified error number with an identifier that has been declared an EXCEPTION in your current program or an accessible package. See the "Exception Handling" section for more information on this pragma.

INLINE

Tells the compiler whether calls to a subprogram should be replaced with a copy of the subprogram. See the "Optimizing Compiler" section for more information on inline optimization.

RESTRICT_REFERENCES

Tells the compiler the purity level of a packaged program. The purity level is the degree to which a program does not read/write database tables and/or package variables. See the "Calling PL/SQL Functions in SQL" section for more information on this pragma.

SERIALLY_REUSABLE

Tells the runtime engine that package data should not persist between references. This is used to reduce per-user memory requirements when the package data is needed only for the duration of the call and not for the duration of the session. See the "Packages" section for more information on this pragma.

Statements

A PL/SQL program is composed of one or more logical statements. A *statement* is terminated by a semicolon delimiter. The physical end-of-line marker in a PL/SQL program is ignored by the compiler, except to terminate a single-line comment (initiated by the -- symbol).

Block Structure

Each PL/SQL program is a *block* consisting of a standard set of elements, identified by keywords (see Figure 1). The block

determines the scope of declared elements and how exceptions are handled and propagated. A block can be *anonymous* or *named.* Named blocks include functions, procedures, packages, and triggers.
Figure 1. The PL/SQL block structure

Here is an example of an anonymous block:

```
DECLARE
   today DATE DEFAULT SYSDATE;
BEGIN
   -- Display the date.
   DBMS_OUTPUT.PUT_LINE ('Today is ' || today);
END;
```

Here is a named block that performs the same action:

```
CREATE OR REPLACE PROCEDURE show_the_date
IS
   today DATE DEFAULT SYSDATE;
BEGIN
   -- Display the date.
   DBMS_OUTPUT.PUT_LINE ('Today is ' || today);
END show_the_date;
```

The following table summarizes the sections of a PL/SQL block:

Section	Description
Header	Required for named blocks. Specifies the way the program is called by other PL/SQL blocks. Anonymous blocks do not have a header. They start with the DECLARE keyword if there is a declaration section, or with the BEGIN keyword if there are no declarations.
Declaration	Optional; declares variables, cursors, TYPEs, and local programs that are used in the block's execution and exception sections.
Execution	Optional in package and TYPE specifications; contains statements that are executed when the block is run.
Exception	Optional; describes error-handling behavior for exceptions raised in the executable section.

Variables and Program Data

PL/SQL programs normally are used to manipulate database information. You commonly do this by declaring variables and data structures in your programs, and then working with that PL/SQL-specific data.

A *variable* is a named instantiation of a data structure declared in a PL/SQL block (either locally or in a package). Unless you declare a variable as a CONSTANT, its value can be changed at any time in your program.

The following table summarizes the different types of program data.

Type	Description
Scalar	Variables made up of a single value, such as a number, date, or Boolean.
Composite	Variables made up of multiple values, such as a record, collection, or instance of a user-defined object type. See the sections "Records in PL/SQL," "Collections in PL/SQL," and "Object-Oriented Features."
Reference	Logical pointers to values or cursors.
LOB	Variables containing large object (LOB) locators.

Scalar Datatypes

Scalar datatypes divide into four families: number, character, datetime, and Boolean. Subtypes further define a base datatype by restricting the values or size of the base datatype.

Numeric datatypes

Numeric datatypes represent real numbers, integers, and floating-point numbers. They are stored as NUMBER, PLS_INTEGER, and IEEE floating-point storage types.

Decimal numeric datatypes store fixed and floating-point numbers of just about any size. They include the subtypes NUMBER, DEC, DECIMAL, NUMERIC, FLOAT, REAL, and DOUBLE PRECISION. The maximum precision of a variable with type NUMBER is 38 digits, which yields a range of values from 1.0E-129 through 9.999E125.

Variables of type NUMBER can be declared with precision and scale, as follows:

```
NUMBER(precision, scale)
```

where *precision* is the number of digits, and *scale* is the number of digits to the right (positive scale) or left (negative scale) of the decimal point at which rounding occurs. Legal values for *scale* range from –84 to 127. The following table shows examples of *precision* and *scale*:

Declaration	Assigned value	Stored value
NUMBER	6.02	6.02
NUMBER(4)	8675	8675
NUMBER(4)	8675309	Error
NUMBER(12,5)	3.14159265	3.14159
NUMBER(12,-5)	8675309	8700000

Oracle provides a variety of datatypes to store 32-bit whole numbers: BINARY_INTEGER, INTEGER, INT, SMALL-INT, NATURAL, NATURALN, POSITIVE, POSITIVEN,

SIGNTYPE, and PLS_INTEGER. Prior to Oracle Database 10*g*, all of these except PLS_INTEGER were manipulated using the same C-language arithmetic library as the NUMBER datatype. The PLS_INTEGER datatype and, starting with Oracle Database 10*g*, all NUMBER datatypes use the speedier machine arithmetic.

Binary integer datatypes store signed integers in the range of $-2^{31} + 1$ to $2^{31} - 1$. The subtypes include NATURAL (0 through $2^{31} - 1$) and POSITIVE (1 through $2^{31} - 1$) together with the NOT NULL variations NATURALN and POSITIVEN. SIGNTYPE is restricted to three values (–1, 0, 1). PLS_INTEGER is an unconstrained subtype (alias) of BINARY_INTEGER.

SIMPLE_INTEGER (introduced in Oracle Database 11*g*) has the same range as BINARY_INTEGER except that it does not allow for NULL values and does not raise an exception if an overflow occurs. For example, 2147483647 + 1 = –2147483648 (note the negative value!). SIMPLE_INTEGER datatypes can result in significantly faster execution speeds when the PL/SQL code is compiled to native machine code.

IEEE 754-compliant floating-point numbers are available in both SQL and PL/SQL. These subtypes are the single-precision BINARY_FLOAT and the double-precision BINARY_DOUBLE. Because these datatypes require less memory and use native machine arithmetic, they perform much better for scientific or engineering applications that are computer-intensive or that require comparison to infinity or Not a Number (NaN). These two datatypes have binary precision instead of the decimal precision used in the NUMBER family. So, if you are developing financial applications that are concerned with rounding errors or require decimal precision, you probably should not use these floating-point datatypes.

The following table lists the PL/SQL numeric datatypes with ANSI and IBM compatibility. In this table:

- *precision* is the precision for the subtype.
- *scale* is the scale of the subtype.
- *binary* is the binary precision of the subtype.

PL/SQL datatype	Compatibility	Oracle database datatype
DEC(*precision*,*scale*)	ANSI	NUMBER(*precision*,*scale*)
DECIMAL(*precision*,*scale*)	IBM	NUMBER(*precision*,*scale*)
DOUBLE PRECISION	ANSI	NUMBER
FLOAT(*binary*)	ANSI, IBM	NUMBER
INT	ANSI	NUMBER(38)
INTEGER	ANSI, IBM	NUMBER(38)
NUMERIC(*precision*,*scale*)	ANSI	NUMBER(*precision*,*scale*)
REAL	ANSI	NUMBER
SMALLINT	ANSI, IBM	NUMBER(38)
BINARY_FLOAT	IEEE 754	BINARY_FLOAT
BINARY_ DOUBLE	IEEE 754	BINARY_ DOUBLE

Character datatypes

Character datatypes store alphanumeric text and are manipulated by character functions. As with the numeric family, there are several subtypes in the character family, shown in the following table:

Family	Description
CHAR	Fixed-length alphanumeric strings. Valid sizes are 1 to 32767 bytes (which is larger than the database limit of 4000).
VARCHAR2	Variable-length alphanumeric strings. Valid sizes are 1 to 32767 bytes (which is larger than the database limit of 4000).
LONG	Variable-length alphanumeric strings. Valid sizes are 1 to 32760 bytes. LONG is included primarily for backward compatibility. CLOB is the preferred datatype for large character strings.

Family	Description
RAW	Variable-length binary strings. Valid sizes are 1 to 32767 bytes (which is larger than the database limit of 2000). RAW data does not undergo character set conversion when selected from a remote database.
LONG RAW	Variable-length binary strings. Valid sizes are 1 to 32760 bytes. LONG RAW is included primarily for backward compatibility. BLOB and BFILE are the preferred datatypes for large binary data.
ROWID	Fixed-length binary data. Every row in a database has a physical address or ROWID. A ROWID has four parts in base 64: *OOOOOOFFFBBBBBBRRR* where: • *OOOOOO* is the object number. • *FFFF* is the absolute or relative file number. • *BBBBBB* is the block number within the file. • *RRR* is the row number within the block.
UROWID	Universal ROWID. Variable-length hexadecimal string depicting a logical, physical, or non-Oracle row identifier. Valid sizes are up to 4000 bytes.

Unicode character datatypes

The standard WE8MSWIN1252 or WE8ISO8859P2 character set does not support some languages, such as Chinese and Greek. To support multiple languages, the database allows two character sets—the *database character set* and a Unicode character set, sometimes called the *national character set* (NLS).

The two NLS datatypes, NCHAR and NVARCHAR2, are used to represent data in the Unicode character set. NCHAR values are fixed-length character data; the maximum length is 32767 bytes. NVARCHAR2 values are variable-length character data; the maximum length also is 32767 bytes.

Datetime datatypes

The datetime datatypes are DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, and TIMESTAMP WITH LOCAL TIME ZONE. There are also two interval datatypes, INTERVAL YEAR TO MONTH and INTERVAL DAY TO SECOND.

DATE values are fixed-length, date-plus-time values. The DATE datatype can store dates from January 1, 4712 B.C. to December 31, 9999 A.D. Each DATE includes the century, year, month, day, hour, minute, and second. Subsecond granularity is not supported via the DATE datatype; use one of the TIMESTAMP datatypes instead. The time portion of a DATE defaults to midnight (12:00:00 a.m.) if it is not included explicitly.

TIMESTAMP values store date and time to subsecond granularity. The subsecond precision (the number of digits to the right of the decimal) either defaults to 6 or is set to 0 through 9 digits by declaration, as in:

```
DECLARE
  mytime_declared TIMESTAMP(9);
  mytime_default  TIMESTAMP; -- default 6 digits precision
```

TIMESTAMP WITH TIME ZONE values store date and time values like a TIMESTAMP but also store the hourly offset from Coordinated Universal Time (UTC, which is essentially equivalent to Greenwich Mean Time). As with TIMESTAMP, the subsecond precision is 0 to 9 digits, either declared or inherited from the default 6 digits of precision:

```
DECLARE
  mytime_declared TIMESTAMP(9) WITH TIME ZONE;
  mytime_default  TIMESTAMP WITH TIME ZONE;
```

TIMESTAMP WITH LOCAL TIME ZONE values store date and time values together with the UTC offset, like a TIMESTAMP WITH TIME ZONE. The principal difference between these timestamp datatypes occurs when values are saved to or retrieved from a database table. TIMESTAMP WITH LOCAL TIME ZONE values are converted to the database time zone and saved without an offset. The values retrieved from the database table are converted from the database time zone to the session's time zone.

The offset from UTC for both TIMESTAMP WITH TIME ZONE and TIMESTAMP WITH LOCAL TIME ZONE can be hours and minutes or a time zone region (found in the

V\$TIMEZONE_NAMES data dictionary view) with the optional daylight savings time name (also found in V\$TIMEZONE_NAMES). For example:

```
ALTER SESSION SET NLS_TIMESTAMP_TZ_FORMAT=
   'DD-Mon-YYYY HH24:MI:SS.FF TZR';
DECLARE
   my_tswtz    TIMESTAMP(4) WITH TIME ZONE;
BEGIN
   my_tswtz := '31-MAR-2007 07:32:45.1234 US/Pacific';
```

INTERVAL YEAR TO MONTH values store a period of time in years and months:

```
DECLARE
   myy2m INTERVAL YEAR TO MONTH;
BEGIN
   myy2m := INTERVAL '1-6' YEAR TO MONTH;
```

INTERVAL DAY TO SECOND values store a period of time in days, hours, minutes, seconds, and fractional seconds:

```
DECLARE
   myd2s INTERVAL DAY TO SECOND;
BEGIN
   myd2s := INTERVAL '2 10:32:15.678' DAY TO SECOND;
```

BOOLEAN datatype

The BOOLEAN datatype can store one of only three values: TRUE, FALSE, or NULL. BOOLEAN variables usually are used in logical control structures such as IF…THEN or LOOP statements.

The following truth tables show the results of logical AND, OR, and NOT operations with PL/SQL's three-value Boolean model:

AND	TRUE	FALSE	NULL
TRUE	TRUE	FALSE	NULL
FALSE	FALSE	FALSE	FALSE
NULL	NULL	FALSE	NULL

OR	TRUE	FALSE	NULL
TRUE	TRUE	TRUE	TRUE
FALSE	TRUE	FALSE	NULL
NULL	TRUE	NULL	NULL

NOT (TRUE)	NOT (FALSE)	NOT (NULL)
FALSE	TRUE	NULL

LOB Datatypes

PL/SQL supports a number of large object (LOB) datatypes, which can store objects of up to four gigabytes of data. Unlike the scalar datatypes, variables declared for LOBs use *locators*, or pointers to the actual data. LOBs are manipulated in PL/SQL using the built-in package DBMS_LOB. The LOB datatypes are:

BFILE

File locators pointing to read-only large binary objects in operating system files. With BFILEs, the large objects are outside the database.

BLOB

LOB locators that point to large binary objects inside the database.

CLOB

LOB locators that point to large character (alphanumeric) objects inside the database.

NCLOB

LOB locators that point to large Unicode character objects inside the database.

Implicit Datatype Conversions

Whenever PL/SQL detects that a datatype conversion is necessary, it attempts to change the values as required to perform the operation. Figure 2 shows what types of implicit conversions PL/SQL can perform. Note that not all values in each datatype can be converted to another datatype. For example, an attempt to convert BINARY_FLOAT_NAN to a number datatype will raise an INVALID NUMBER exception.

NULLs in PL/SQL

PL/SQL represents unknown or inapplicable values as NULL values. Because a NULL is unknown, a NULL is never equal or not equal to anything (including another NULL value). In addition, most functions return a NULL when passed a NULL argument—the notable exceptions are NVL, NVL2, CONCAT, and REPLACE. You cannot check for equality or inequality to NULL; therefore, you must use the IS NULL or IS NOT NULL syntax to check for NULL values.

Here is an example of the IS NULL syntax used to check the value of a variable:

```
BEGIN
    IF myvar IS NULL
    THEN
        ...
```

Declaring Variables

Before you can use a variable, you must first declare it in the declaration section of your PL/SQL block or in a package as a global. When you declare a variable, PL/SQL allocates memory for the variable's value and names the storage location so that the value can be retrieved and changed. The syntax for a variable declaration is:

```
variable_name [CONSTANT] datatype [NOT NULL]
    [{ := | DEFAULT } initial_value];
```

Figure 2. Implicit conversions attempted by PL/SQL

Rows indicate the **From** type; columns indicate the **To** type. A bullet (•) marks an implicit conversion attempted by PL/SQL; shaded (blank) cells on the diagonal mark identical types.

From ＼ To	CHAR	VARCHAR2	NCHAR	NVARCHAR2	DATE	DATETIME/ INTERVAL	NUMBER	BINARY_ FLOAT	BINARY_ DOUBLE	BINARY_ INTEGER	PLS_ INTEGER	SIMPLE_ INTEGER	LONG	RAW	ROWID	CLOB	BLOB	NCLOB

CLOB	•	•	•	•									•					•
BLOB														•				
NCLOB	•	•	•	•									•			•		

Constrained declarations

The datatype in a declaration can be constrained or unconstrained. Constrained datatypes have a size, scale, or precision limit that is less than the unconstrained datatype. For example:

```
total_sales    NUMBER(15,2);   -- Constrained.
emp_id         VARCHAR2(9);    -- Constrained.
company_number NUMBER;         -- Unconstrained.
book_title     VARCHAR2;       -- Not valid.
```

Constrained declarations require less memory than unconstrained declarations. Not all datatypes can be specified as unconstrained. You cannot, for example, declare a variable to be of type VARCHAR2. You must always specify the maximum size of a variable-length string.

Constants

The CONSTANT keyword in a declaration requires an initial value and does not allow that value to be changed. For example:

```
min_order_qty   NUMBER(1) CONSTANT := 5;
```

Default values

Whenever you declare a variable, it is assigned a default value of NULL.* Initializing all variables is distinctive to PL/SQL; in this way, PL/SQL differs from languages such as C and Ada. If you want to initialize a variable to a value other than NULL, you do so in the declaration with either the assignment operator (:=) or the DEFAULT keyword:

```
counter  BINARY_INTEGER := 0;
priority VARCHAR2(8)    DEFAULT 'LOW';
```

---

* There is an exception to this rule: associative arrays are *not* null when declared, and there is no way to make them null. However, when declared, associative arrays have no elements, a state unsurprisingly known as "empty."

A NOT NULL constraint can be appended to the variable's datatype declaration to indicate that NULL is not a valid value. If you add the NOT NULL constraint, you must explicitly assign an initial value for that variable.

Anchored Declarations

Use the %TYPE attribute to *anchor* the datatype of a scalar variable to either another variable or to a column in a database table or view. Use %ROWTYPE to anchor a record's declaration to a cursor or table (see the later section, "Records in PL/SQL," for more details on the %ROWTYPE attribute).

The following block shows several variations of anchored declarations:

```
DECLARE
   tot_sales NUMBER(20,2);
   -- Anchor to a PL/SQL variable.
   monthly_sales tot_sales%TYPE;

   -- Anchor to a database column.
   v_ename employee.last_name%TYPE;

   CURSOR mycur IS
      SELECT * FROM employee;

   -- Anchor to a cursor.
   myrec mycur%ROWTYPE;
```

The NOT NULL clause on a variable declaration (but not on a database column definition) follows the %TYPE anchoring and requires anchored declarations to have a default in their declaration. The default value for an anchored declaration can be different from that for the base declaration:

```
tot_sales    NUMBER(20,2) NOT NULL DEFAULT 0;
monthly_sales tot_sales%TYPE DEFAULT 10;
```

Programmer-Defined Subtypes

PL/SQL allows you to define unconstrained scalar subtypes. An unconstrained subtype provides an alias to the original underlying datatype; for example:

```
CREATE OR REPLACE PACKAGE std_types
IS
   -- Declare standard types as globals.
   SUBTYPE dollar_amt_t IS NUMBER;
END std_types;

CREATE OR REPLACE PROCEDURE process_money
IS
   -- Use the global type declared above.
   credit std_types.dollar_amt_t;
```

A constrained subtype limits or constrains the new datatype to a subset of the original datatype. For example, POSITIVE is a constrained subtype of BINARY_INTEGER. The declaration for POSITIVE in the STANDARD package is:

```
SUBTYPE POSITIVE IS BINARY_INTEGER RANGE 1.. 2147483647;
```

You can define your own constrained subtypes in your programs:

```
PACKAGE std_types
IS
   SUBTYPE currency_t IS NUMBER (15, 2);
END;
```

Conditional and Sequential Control

PL/SQL includes conditional (IF, CASE) structures as well as sequential control (GOTO, NULL) constructs.

Conditional Control Statements

There are several varieties of IF-THEN-ELSE and CASE structures.

IF-THEN combination

```
IF condition THEN
   executable statement(s)
END IF;
```

For example:

```
IF caller_type = 'VIP' THEN
   generate_response('GOLD');
END IF;
```

IF-THEN-ELSE combination

```
IF condition THEN
   TRUE sequence_of_executable_statement(s)
ELSE
   FALSE/NULL sequence_of_executable_statement(s)
END IF;
```

For example:

```
IF caller_type = 'VIP' THEN
   generate_response('GOLD');
ELSE
   generate_response('BRONZE');
END IF;
```

IF-THEN-ELSIF combination

```
IF condition-1 THEN
   statements-1
ELSIF condition-N THEN
 statements-N
[ELSE
   ELSE statements]
END IF;
```

For example:

```
IF caller_type = 'VIP' THEN
   generate_response('GOLD');
ELSIF priority_client THEN
   generate_response('SILVER');
ELSE
   generate_response('BRONZE');
END IF;
```

CASE statement

There are two types of CASE statements: simple and searched.

A simple CASE statement is similar to an IF-THEN-ELSIF structure. The statement has a switch expression immediately after the keyword CASE. The expression is evaluated and compared to the value in each WHEN clause. The first WHEN clause with a matching value is executed, and then control passes to the next statement following the END CASE. For example:

```
CASE region_id
   WHEN 'NE' THEN
      mgr_name := 'MINER';
   WHEN 'SE' THEN
      mgr_name := 'KOOI';
   ELSE mgr_name := 'LANE';
END CASE;
```

If a switch expression evaluates to NULL, the ELSE case is the only one that can possibly match; WHEN NULL will never match because the database performs an equality comparison on the expressions.

Both the CASE statement and the CASE expression (see the next section) should include an ELSE clause that will execute statements if no WHEN clause evaluates to TRUE, because PL/SQL's runtime engine will raise an exception if it finds no matching expression.

The searched CASE statement does not have a switch; instead, each WHEN clause has a complete Boolean expression. The first matching WHEN clause is executed, and control passes to the next statement following the END CASE; for example:

```
CASE
   WHEN region_id = 'EAME' THEN
      mgr_name := 'SCHMIDT';
   WHEN division = 'SALES' THEN
      mgr_name := 'KENNEDY';
   ELSE mgr_name := 'GUPTA';
END CASE;
```

CASE expression

There are also two types of CASE expressions: simple and searched. You can use CASE expressions anywhere that expressions are valid in your SQL or PL/SQL programs.

A simple CASE expression lets you choose an expression to evaluate based on a scalar value that you provide as input. The following example shows a simple CASE expression being used with the built-in DBMS_OUTPUT package to output the value of a Boolean variable. DBMS_OUTPUT.PUT_LINE is not overloaded to handle Boolean types, so in this example, the CASE expression converts the Boolean value in a character string, which PUT_LINE can then handle:

```
DECLARE
    boolean_true BOOLEAN := TRUE;
    boolean_false BOOLEAN := FALSE;
    boolean_null BOOLEAN;

    FUNCTION boolean_to_varchar2 (flag IN BOOLEAN)
       RETURN VARCHAR2 IS
    BEGIN
       RETURN
          CASE flag
             WHEN TRUE THEN 'True'
             WHEN FALSE THEN 'False'
             ELSE 'NULL'
          END;
    END;

BEGIN
    DBMS_OUTPUT.PUT_LINE(boolean_to_varchar2
       (boolean_true));
    DBMS_OUTPUT.PUT_LINE(boolean_to_varchar2
       (boolean_false));
    DBMS_OUTPUT.PUT_LINE(boolean_to_varchar2
       (boolean_null));
END;
```

A searched CASE expression evaluates a list of expressions to find the first one that evaluates to TRUE, and then returns the results of an associated expression. In the following example, a searched CASE expression returns the proper bonus value for any given salary:

```
DECLARE
  salary NUMBER := 20000;
  employee_id NUMBER := 36325;

  PROCEDURE give_bonus
    (emp_id IN NUMBER, bonus_amt IN NUMBER) IS
  BEGIN
    DBMS_OUTPUT.PUT_LINE(emp_id);
    DBMS_OUTPUT.PUT_LINE(bonus_amt);
  END;

BEGIN
   give_bonus(employee_id,
      CASE
         WHEN salary >= 10000 AND salary <=20000 THEN 1500
         WHEN salary > 20000 AND salary <= 40000 THEN 1000
         WHEN salary > 40000 THEN 500
         ELSE 0
      END);
END;
```

Sequential Control Statements

PL/SQL provides a GOTO statement and a NULL statement to aid in sequential control operations.

GOTO

The GOTO statement performs unconditional branching to a named label. You should only rarely use a GOTO. At least one executable statement must follow the label (the NULL statement can be this necessary executable statement). The format of a GOTO statement is:

```
GOTO label_name;
```

For example:

```
BEGIN
   GOTO second_output;

   DBMS_OUTPUT.PUT_LINE('This line will never execute.');

   <<second_output>>
   DBMS_OUPUT.PUT_LINE('We are here!');
END
```

There are several scope restrictions on where a GOTO can branch control. A GOTO:

- Can branch out of an IF statement, LOOP, or subblock
- Cannot branch into an IF statement, LOOP, or subblock
- Cannot branch from one section of an IF statement to another (from the IF-THEN section to the ELSE section is illegal)
- Cannot branch into or out of a subprogram
- Cannot branch from the exception section to the executable section of a PL/SQL block
- Cannot branch from the executable section to the exception section of a PL/SQL block, although a RAISE does this

NULL

The NULL statement is an executable statement that does nothing. It is useful when an executable statement must follow a GOTO label or to aid readability in an IF-THEN-ELSE structure. For example:

```
IF :report.selection = 'DETAIL' THEN
   exec_detail_report;
ELSE
   NULL;
END IF;
```

Loops

The LOOP construct allows you to execute a sequence of statements repeatedly. There are three types of loops: simple (infinite), FOR, and WHILE.

You can use the EXIT statement to break out of the LOOP and pass control to the statement following the END LOOP. Use the CONTINUE statement (Oracle Database 11*g*), described later, to break out of the current loop iteration and pass control to the next loop iteration.

Simple Loop

```
LOOP
    executable_statement(s)
END LOOP;
```

The simple loop should contain an EXIT or EXIT WHEN unless you want it to execute infinitely. Use the simple loop when you want the body of the loop to execute at least once. For example:

```
LOOP
    FETCH company_cur INTO company_rec;
    EXIT WHEN company_cur%ROWCOUNT > 5 OR
        company_cur%NOTFOUND;
    process_company(company_cur);
END LOOP;
```

Numeric FOR Loop

```
FOR loop_index IN [REVERSE] lowest_number..highest_number
LOOP
    executable_statement(s)
END LOOP;
```

The PL/SQL runtime engine automatically declares the loop index a PLS_INTEGER variable; never declare a variable with that name yourself. The *lowest_number* and *highest_number* ranges can be variables, but are evaluated only once—on initial entry into the loop. The REVERSE keyword causes PL/SQL to start with the *highest_number* and decrement down to the *lowest_number*. For example, this code:

```
BEGIN
    FOR counter IN 1 .. 4
    LOOP
        DBMS_OUTPUT.PUT(counter);
    END LOOP;
    DBMS_OUTPUT.NEW_LINE;

    FOR counter IN REVERSE 1 .. 4
    LOOP
        DBMS_OUTPUT.PUT(counter);
    END LOOP;
    DBMS_OUTPUT.NEW_LINE;
END;
```

yields the following output:

```
1234
4321
```

Cursor FOR Loop

```
FOR loop_index IN [cursor_name | (SELECT statement)]
LOOP
   executable_statement(s)
END LOOP;
```

The PL/SQL runtime engine automatically declares the loop index as a record of *cursor_name*%ROWTYPE; never declare a variable with that name yourself.

The cursor FOR loop automatically opens the cursor, fetches all rows identified by the cursor, and then closes the cursor. You can embed the SELECT statement directly in the cursor FOR loop or use a previously declared cursor; for example:

```
FOR emp_rec IN emp_cur
LOOP
   IF emp_rec.title = 'Oracle Programmer'
   THEN
      give_raise(emp_rec.emp_id,30)
   END IF;
END LOOP;
```

The cursor FOR loop is an elegant, *declarative* construct (you tell the database to fetch every row in the cursor without specifying *how* to do it). Oracle Database 10*g* and above also optimize it automatically to execute like a BULK COLLECT statement. If, however, your cursor FOR loop contains Data Manipulation Language (DML) statements, you may still want to consider refactoring your code to explicitly use BULK COLLECT and FORALL. See the "Bulk Binds" section for information on these statements.

WHILE Loop

```
WHILE condition
LOOP
   executable_statement(s)
END LOOP;
```

Use the WHILE loop in cases where you may not want the loop body to execute even once:

```
WHILE NOT end_of_analysis
LOOP
   perform_analysis;
   get_next_record;
   IF analysis_cursor%NOTFOUND AND next_step IS NULL
   THEN
      end_of_analysis := TRUE;
   END IF;
END LOOP;
```

REPEAT UNTIL Loop Emulation

PL/SQL does not directly support a REPEAT UNTIL construct, but a modified simple loop can emulate one. The syntax for this emulated REPEAT UNTIL loop is:

```
LOOP
   executable_statement(s)
   EXIT WHEN boolean_condition;
END LOOP;
```

Use the emulated REPEAT UNTIL loop when executing iterations indefinitely before conditionally terminating the loop.

EXIT Statement

```
EXIT [WHEN condition];
```

If you do not include a WHEN clause in the EXIT statement, it will terminate the loop unconditionally. Otherwise, the loop terminates only if the Boolean *condition* evaluates to TRUE. The EXIT statement is optional and can appear anywhere in the loop.

CONTINUE Statement (Oracle Database 11g)

The CONTINUE statement terminates the current iteration of a loop, passing control to the next iteration. The format of a CONTINUE statement is:

```
CONTINUE label_name [WHEN boolean_expression];
```

The optional *label_name* identifies which loop to terminate. If no *label_name* is specified, the innermost loop's current iteration is terminated.

Like the EXIT statement, the CONTINUE statement is optional and can appear anywhere in the loop. The CONTINUE statement can be used to pass control out of a loop, optionally crossing loop boundaries, but cannot pass control out across a procedure, function, or method boundary.

The following example uses CONTINUE to branch out of an inner loop as well an outer loop:

```
DECLARE
  TYPE dow_tab_t IS TABLE OF VARCHAR2(10);
  dow_tab dow_tab_t := dow_tab_t('Sunday'
     ,'Monday','Tuesday','Wednesday','Thursday'
     ,'Friday','Saturday');
BEGIN
  <<day_loop>>
  FOR counter IN 2 .. 6 LOOP
    --Skip Wednesdays
    CONTINUE day_loop WHEN dow_tab(counter)='Wednesday';
    DBMS_OUTPUT.PUT_LINE (dow_tab(counter));
  END LOOP;
END;
```

This yields the following output:

```
Monday
Tuesday
Thursday
Friday
```

This example shows how control may be passed from within an inner loop to the next iteration of an outer loop:

```
DECLARE
BEGIN
  <<outer_loop>>
  FOR outer_counter IN 1 .. 3 LOOP
    DBMS_OUTPUT.PUT_LINE(outer_counter);
    <<inner_loop>>
    FOR inner_counter IN 10 .. 15 LOOP
      CONTINUE outer_loop WHEN outer_counter > 1  AND
          inner_counter = 12;
```

```
      DBMS_OUTPUT.PUT_LINE('...'||inner_counter);
    END LOOP;
  END LOOP;
END;
```

This yields the following output:

```
1
...10
...11
...12
...13
...14
...15
2
...10
...11
3
...10
...11
```

Loop Labels

Loops can be optionally labeled to improve readability and execution control, as shown earlier in the discussion of the GOTO statement. The label must appear immediately in front of the statement that initiates the loop.

The following example demonstrates the use of loop labels to qualify variables within a loop and also to terminate nested and outer loops:

```
<<year_loop>>
FOR yearind IN 1 .. 20
LOOP
    <<month_loop>>
    LOOP
       ...
       IF year_loop.yearind > 10
       THEN
          EXIT year_loop;
       END IF;
    END LOOP month_loop;
END LOOP year_loop;
```

Database Interaction

PL/SQL is tightly integrated with the underlying SQL layer of the Oracle database. You can execute SQL statements (UPDATE, INSERT, DELETE, MERGE, and SELECT) directly in PL/SQL programs. You also can execute Data Definition Language (DDL) statements through the use of dynamic SQL. In addition, you can manage transactions with COMMIT, ROLLBACK, and other Data Control Language (DCL) statements.

Sequences in PLSQL

Sequences are frequently used to generate keys in an Oracle database. To assign a sequence's NEXTVAL or CURRVAL to a PLSQL variable, select the pseudo-column from the table DUAL, like this:

```
SELECT my_sequence.NEXTVAL INTO my_variable FROM dual;
```

Starting with Oracle Database 11*g*, you can reference the sequence pseudo-columns anywhere in your programs in which a number expression can appear. For example:

```
my_variable := my_sequence.NEXTVAL;
```

Transaction Management

The Oracle database provides a transaction model based on a unit of work. The PL/SQL language supports most, but not all, of the database model for transactions (you cannot, for example, specify ROLLBACK FORCE). A transaction begins with the first change to data and ends with either a COMMIT or a ROLLBACK. Transactions are independent of PL/SQL blocks. Transactions can span multiple PL/SQL blocks, or multiple transactions can be in a single PL/SQL block. The PL/SQL-supported transaction statements include COMMIT, ROLLBACK, SAVEPOINT, SET TRANSACTION, and LOCK TABLE, described in the following sections.

COMMIT

```
COMMIT [WORK] [comment_text];
```

COMMIT makes the database changes permanent and visible to other database sessions. The WORK keyword is optional and aids only readability—it is rarely used. The COMMENT text is optional and can be up to 50 characters in length. It is germane only to in-doubt distributed (two-phase commit) transactions. The database statement COMMIT FORCE, also for distributed transactions, is not supported in PL/SQL.

ROLLBACK

```
ROLLBACK [WORK] [TO [SAVEPOINT] savepoint_name];
```

ROLLBACK undoes the changes made in the current transaction either to the beginning of the transaction or to a *savepoint*. A savepoint is a named processing point in a transaction, created with the SAVEPOINT statement. Rolling back to a savepoint is a partial rollback of a transaction, wiping out all changes (and savepoints) that occurred later than the named savepoint.

SAVEPOINT

```
SAVEPOINT savepoint_name;
```

SAVEPOINT establishes a savepoint in the current transaction. *savepoint_name* is an undeclared identifier. More than one savepoint can be established within a transaction. If you reuse a savepoint name, that savepoint is moved to the later position and you will not be able to roll back to the initial savepoint position.

SET TRANSACTION

```
SET TRANSACTION READ ONLY;
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET TRANSACTION USE ROLLBACK SEGMENT rbseg_name;
```

SET TRANSACTION has three transaction control functions:

READ ONLY

> This marks the beginning of a read-only transaction. It indicates to the Oracle database that a read-consistent view of the database is to be enforced for the transaction (the default is for the statement). This read-consistent view means that only changes committed before the transaction begins are visible for the duration of the transaction. The transaction is ended with either a COMMIT or a ROLLBACK. Only LOCK TABLE, SELECT, SELECT INTO, OPEN, FETCH, CLOSE, COMMIT, and ROLLBACK statements are permitted during a read-only transaction. Issuing other statements, such as INSERT or UPDATE, in a read-only transaction results in an ORA-1456 error.

ISOLATION LEVEL SERIALIZABLE

> Similar to a READ ONLY transaction in that transaction-level read consistency is enforced rather than the default statement-level read consistency. Serializable transactions do allow changes to data, however.

USE ROLLBACK SEGMENT

> If your database is using rollback segments for undo management, as opposed to automatic undo management, this statement tells the database to use the specifically named rollback segment *rbseg_name*. For example, if we know that our large rollback segment is named rbs_large, we can tell the database to use it by issuing the following statement before our first change to data:
>
>   SET TRANSACTION USE ROLLBACK SEGMENT rbs_large;

LOCK TABLE

    LOCK TABLE table_list IN lock_mode MODE [NOWAIT];

This statement bypasses the implicit database row-level locks by explicitly locking one or more tables in the specified mode. The *table_list* is a comma-delimited list of tables. The

---

lock_mode is one of the following: ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE, SHARE, SHARE ROW EXCLUSIVE, or EXCLUSIVE. The NOWAIT keyword specifies that the Oracle database should not wait for a lock to be released. If there is a lock when NOWAIT is specified, the database raises the exception "ORA-00054: resource busy and acquire with NOWAIT specified." The default database locking behavior is to wait indefinitely.

Autonomous Transactions

Autonomous transactions execute within a block of code as separate transactions from the outer (main) transaction. Changes can be committed or rolled back in an autonomous transaction without committing or rolling back the main transaction. Changes committed in an autonomous transaction are visible to the main transaction, even though they occur after the start of the main transaction. Those changes committed in an autonomous transaction are visible to other transactions as well. The database suspends the main transaction while the autonomous transaction executes:

```
PROCEDURE main IS
BEGIN
   UPDATE ... -- Main transaction begins here.
   DELETE ...
   at_proc;   -- Call the autonomous transaction.
   SELECT ...
   INSERT ...
   COMMIT;    -- Main transaction ends here.
END;

PROCEDURE at_proc IS
   PRAGMA AUTONOMOUS_TRANSACTION;
BEGIN          -- Main transaction suspends here.
   SELECT ...
   INSERT ... -- Autonomous transaction begins here.
   UPDATE ...
   DELETE ...
   COMMIT;    -- Autonomous transaction ends here.
END;           -- Main transaction resumes here.
```

So, changes made in the main transaction are not visible to the autonomous transaction, and if the main transaction holds any locks that the autonomous transaction waits for, a deadlock occurs. Using the NOWAIT option on UPDATE statements in autonomous transactions can help to minimize this kind of deadlock. Functions and procedures (local program, standalone, or packaged), database triggers, top-level anonymous PL/SQL blocks, and object methods can be declared autonomous via the compiler directive PRAGMA AUTONOMOUS_TRANSACTION. In addition, there must be a COMMIT or a ROLLBACK at each exit point in the autonomous program.

Cursors in PL/SQL

Every SQL statement executed by the Oracle database has a private SQL area that contains information about the SQL statement and the set of data returned. In PL/SQL, a *cursor* is a name assigned to a specific private SQL area for a specific SQL statement. There can be either *static cursors*, whose SQL statement is determined at compile time, or *dynamic cursors*, whose SQL statement is determined at runtime.

Static cursors are used only for DML statements (SELECT, INSERT, UPDATE, DELETE, MERGE, or SELECT FOR UPDATE). These static cursors may be explicitly declared and named or may appear inline as implicit cursors.

Dynamic cursors are used for any type of valid SQL statement including DDL (CREATE, TRUNCATE, ALTER) and DCL (GRANT, REVOKE). Dynamic cursors are implemented with the EXECUTE IMMEDIATE statement.

Explicit Cursors

Explicit cursors are SELECT statements that are DECLAREd explicitly in the declaration section of the current block or in a package specification. Use OPEN, FETCH, and CLOSE in the execution or exception sections of your programs.

Declaring explicit cursors

To use an explicit cursor, you must first declare it in the declaration section of a block or package. There are three types of explicit cursor declarations:

- A cursor without parameters; for example:

```
CURSOR company_cur
    IS
    SELECT company_id FROM company;
```

- A cursor that accepts arguments through a parameter list; for example:

```
CURSOR company_cur (id_in IN NUMBER)
    IS
    SELECT name FROM company
     WHERE  company_id = id_in;
```

- A cursor header that contains a RETURN clause in place of the SELECT statement; for example:

```
CURSOR company_cur (id_in IN NUMBER)
RETURN company%ROWTYPE;
```

This last example shows that the cursor can be declared separately from its implementation—for example, the header in a package specification and the implementation in the package body. See the later section, "Packages," for more information.

Opening explicit cursors

To open a cursor, use the following syntax:

```
OPEN cursor_name [(argument [,argument ...])];
```

where *cursor_name* is the name of the cursor as declared in the declaration section. The arguments are required if the definition of the cursor contains a parameter list.

You must open an explicit cursor before you can fetch rows from that cursor. When the cursor is opened, the processing actually includes the parse, bind, open, and execute phases of SQL statement execution. This OPEN processing includes determining an execution plan, associating host variables and cursor parameters with the placeholders in the SQL

statement, determining the result set, and, finally, setting the current row pointer to the first row in the result set.

When using a cursor FOR loop, the OPEN is implicit in the FOR statement. If you try to open a cursor that is already open, PL/SQL will raise an "ORA-06511: PL/SQL: cursor already open" exception.

Fetching from explicit cursors

The FETCH statement places the contents of the current row into local variables. To retrieve all rows in a result set, each row needs to be fetched. The syntax for a FETCH statement is:

```
FETCH cursor_name INTO record_or_variable_list;
```

where *cursor_name* is the name of the cursor as declared and opened.

Closing explicit cursors

After all rows have been fetched, a cursor needs to be closed. Closing a cursor enables the PL/SQL memory optimization algorithm to release the associated memory at an appropriate time. You can close an explicit cursor by specifying a CLOSE statement as follows:

```
CLOSE cursor_name;
```

where *cursor_name* is the name of the cursor declared and opened.

If you declare a cursor in a local anonymous, procedure, or function block, that cursor will close automatically when the block terminates. Package-based cursors must be closed explicitly, or they stay open for the duration of your session. Closing a cursor that is not open raises an INVALID_ CURSOR exception.

Explicit cursor attributes

There are four attributes associated with cursors: ISOPEN, FOUND, NOTFOUND, and ROWCOUNT. These attributes can be accessed with the % delimiter to obtain information about the state of the cursor. The syntax for a cursor attribute is:

cursor_name%attribute

where *cursor_name* is the name of the explicit cursor.

The behaviors of the explicit cursor attributes are described in the following table:

Attribute	Description
%ISOPEN	TRUE if cursor is open. FALSE if cursor is not open.
%FOUND	INVALID_CURSOR is raised if cursor has not been OPENed. NULL before the first fetch. TRUE if record was fetched successfully. FALSE if no row was returned. INVALID_CURSOR if cursor has been CLOSEd.
%NOTFOUND	INVALID_CURSOR is raised if cursor has not been OPENed. NULL before the first fetch. FALSE if record was fetched successfully. TRUE if no row was returned. INVALID_CURSOR if cursor has been CLOSEd.
%ROWCOUNT	INVALID_CURSOR is raised if cursor has not been OPENed. The number of rows fetched from the cursor. INVALID_CURSOR if cursor has been CLOSEd.

Frequently, a cursor attribute is checked as part of a loop that fetches rows from a cursor, as shown here:

```
DECLARE
   caller_rec caller_pkg.caller_cur%ROWTYPE;
BEGIN
   OPEN caller_pkg.caller_cur;
```

```
   LOOP
      FETCH caller_pkg.caller_cur into caller_rec;
      EXIT WHEN caller_pkg.caller_cur%NOTFOUND
                 OR
                 caller_pkg.caller_cur%ROWCOUNT > 10;

      UPDATE call
         SET caller_id = caller_rec.caller_id
         WHERE call_timestamp < SYSDATE;
   END LOOP;
   CLOSE caller_pkg.caller_cur;
END;
```

Implicit Cursors

Whenever a SQL statement is directly in the execution or exception section of a PL/SQL block, you are working with implicit cursors. SQL statements handled this way include INSERT, UPDATE, DELETE, MERGE, and SELECT INTO. Unlike explicit cursors, implicit cursors do not need to be DECLAREd, OPENed, FETCHed, or CLOSEd.

SELECT statements handle the %FOUND and %NOT-FOUND attributes differently from the way that explicit cursors do. When an implicit SELECT statement does not return any rows, PL/SQL immediately raises the NO_DATA_FOUND exception, and control passes to the exception section. When an implicit SELECT returns more than one row, PL/SQL immediately raises the TOO_MANY_ROWS exception, and control passes to the exception section.

Implicit cursor attributes are referenced via the SQL cursor. For example:

```
BEGIN
   UPDATE activity SET last_accessed := SYSDATE
   WHERE UID = user_id;

   IF SQL%NOTFOUND THEN
      INSERT INTO activity_log (uid,last_accessed)
      VALUES (user_id,SYSDATE);
   END IF
END;
```

The following table lists the implicit cursor attributes:

Attributes	Description
SQL%ISOPEN	Always FALSE because the cursor is opened implicitly and closed immediately after the statement is executed.
SQL%FOUND	NULL before the statement. TRUE if one or more rows were inserted, merged, updated, or deleted, or if only one row was selected. FALSE if no row was selected, merged, updated, inserted, or deleted.
SQL%NOTFOUND	NULL before the statement. TRUE if no row was selected, merged, updated, inserted, or deleted. FALSE if one or more rows were inserted, merged, updated, or deleted.
SQL%ROWCOUNT	Number of rows affected by the cursor.
SQL%BULK_ ROWCOUNT	Pseudo-associative array (index-by table) containing the number of rows affected by the statements executed in bulk bind operations. See the "Bulk Binds" section for more information.

Use the RETURNING clause in INSERT, UPDATE, and DELETE statements to obtain data modified by the associated DML statement. This clause allows you to avoid an additional SELECT statement to query the results of the DML statement. For example:

```
BEGIN
   UPDATE activity SET last_accessed := SYSDATE
   WHERE UID = user_id
   RETURNING last_accessed, cost_center
   INTO timestamp, chargeback_acct;
```

SELECT FOR UPDATE clause

By default, the Oracle database locks rows as they are changed. To lock all rows in a result set, use the FOR UPDATE clause in your SELECT statement when you OPEN the cursor, instead of when you change the data. Using the FOR UPDATE clause does not require you to actually make

changes to the data; it only locks the rows when opening the cursor. These locks are released on the next COMMIT or ROLLBACK. As always, these row locks do not affect other SELECT statements unless they, too, are FOR UPDATE. The FOR UPDATE clause is appended to the end of the SELECT statement and has the following syntax:

```
SELECT ...
  FROM ...
   FOR UPDATE [OF column_reference] [NOWAIT];
```

where *column_reference* is a comma-delimited list of columns that appear in the SELECT clause. The NOWAIT keyword tells the Oracle database to not wait for other blocking locks to be released. The default is to wait forever.

In the following example, only columns from the inventory (pet) table are referenced FOR UPDATE, so no rows in the dog_breeds (dog) table are locked when hounds_in_stock_cur is opened:

```
DECLARE
   CURSOR hounds_in_stock_cur IS
      SELECT pet.stock_no, pet.breeder, dog.size
        FROM dog_breeds dog, inventory pet
       WHERE dog.breed = pet.breed
         AND dog.class = 'HOUND'
         FOR UPDATE OF pet.stock_no, pet.breeder;
BEGIN
```

WHERE CURRENT OF clause

UPDATE and DELETE statements can use a WHERE CURRENT OF clause if they reference a cursor declared FOR UPDATE. This syntax indicates that the UPDATE or DELETE statement should modify the current row identified by the FOR UPDATE cursor. The syntax is:

```
[UPDATE | DELETE ] ...
   WHERE CURRENT OF cursor_name;
```

By using WHERE CURRENT OF, you do not have to repeat the WHERE clause in the SELECT statement. For example:

```
DECLARE
   CURSOR wip_cur IS
      SELECT acct_no, enter_date FROM wip
       WHERE enter_date < SYSDATE - 7
         FOR UPDATE;
BEGIN
   FOR wip_rec IN wip_cur
   LOOP
      INSERT INTO acct_log (acct_no, order_date)
         VALUES (wip_rec.acct_no, wip_rec.enter_date);
      DELETE FROM wip
         WHERE CURRENT OF wip_cur;
   END LOOP;
END;
```

Dynamic Cursors

Dynamic cursors are implemented with an EXECUTE IMMEDIATE statement together with the OPEN FOR, FETCH, and CLOSE statements. The EXECUTE IMMEDIATE statement supports single-row queries and DDL, while the OPEN FOR, FETCH, and CLOSE statements support dynamic multirow queries. Here is the syntax for these statements:

```
EXECUTE IMMEDIATE sql_statement
  [INTO {variable [,variable ...] | record}]
  [USING [IN | OUT | IN OUT] bind_argument
    [,[IN | OUT | IN OUT] bind_argument ...] ]
  [{RETURNING | RETURN} INTO bind_argument
    [,bind_argument]...];
```

The *sql_statement* is passed as an expression in the character datatype family. In Oracle Database 11*g*, your *sql_statement* can also be in a CLOB, thereby allowing you to execute statements larger than 32K. The EXECUTE IMMEDIATE statement parses and executes the SQL statement in a single step. The EXECUTE IMMEDIATE statement requires a

terminating semicolon, but the *sql_statement* must not[*] have a trailing semicolon. For example:

```
EXECUTE IMMEDIATE 'TRUNCATE TABLE foo';

sql_stmt := 'UPDATE emp SET salary = :new_sal WHERE
    emp_id = :empno';
EXECUTE IMMEDIATE sql_stmt USING 75000, 123
```

The OPEN FOR statement assigns a multirow query to a weakly typed cursor variable. The rows are then FETCHed and the cursor CLOSEd:

```
DECLARE
    TYPE cv_typ IS REF CURSOR;
    cv cv_typ;
    laccount_no NUMBER;
    lbalance NUMBER;
BEGIN
    OPEN cv FOR
        'SELECT account_no, balance
            FROM accounts
          WHERE balance < 500';
    LOOP
        FETCH cv INTO laccount_no, lbalance;
        EXIT WHEN cv%NOTFOUND;
        -- Process the row.
    END LOOP;
    CLOSE cv;
END;
```

DBMS_SQL

The DBMS_SQL built-in package also enables dynamic SQL execution within PL/SQL subprograms. For most dynamic SQL requirements, native dynamic SQL (NDS) is easier and much preferred. For a number of more complex scenarios, however, DBMS_SQL is still the only choice. These scenarios include:

---

[*] Well, most statements, anyway. CREATE OR REPLACE statements and anonymous blocks do require semicolons.

Dynamic SQL method 4

> In this most complex type of dynamic SQL, you do not know either the number of describes (columns in the SELECT list) or binds (bind variables in the WHERE clause). In these circumstances, DBMS_SQL provides precisely the granularity of operations needed to implement the code. The DBMS_SQL.DESCRIBE_COLUMNS procedure also comes in very handy for method 4.

Execute strings with more than 32K characters

> Prior to Oracle Database 11*g*, EXECUTE IMMEDIATE will not allow you to execute such large strings, but you can execute these strings with DBMS_SQL.

Oracle Database 11*g* introduces the DBMS_SQL functions TO_REFCURSOR and TO_CURSOR_NUMBER, which allow you to switch back and forth between DBMS_SQL and native dynamic SQL, taking advantage of the best of both dynamic SQL techniques. See *Oracle PL/SQL Programming* for more details on using DBMS_SQL.

SQL Injection and Bind Variables

SQL injection is a security vulnerability that can occur with dynamic SQL when unintended (malicious) code is injected into a program's dynamic SQL statement. The best defense against SQL injection is to use bind variables. This technique is generally recommended, in any case, because SQL statements usually execute repeatedly, and the use of bind variables reduces the need for parsing. Declare your dynamic cursor with placeholders for bind variables (prefixed with a colon) and then pass the bind arguments to the Oracle database at runtime with a USING clause. The parsed form of the statement will be reused from the shared pool, improving performance. For example:

```
EXECUTE IMMEDIATE 'INSERT INTO hr.regions
  (region_id, region_name) VALUES (:r_id, :r_name)'
  USING  id, name;
```

Cursor Variables

A cursor variable is a data structure that points to a cursor object, which in turn points to the cursor's result set. You can use cursor variables to more easily retrieve rows in a result set from client and server programs. You also can use cursor variables to hide minor variations in queries.

The syntax for a REF_CURSOR type (cursor variable) is:

```
TYPE ref_cursor_name IS REF CURSOR
    [RETURN record_type];
```

If you do not include a RETURN clause, you are declaring a *weak* REF CURSOR. Cursor variables declared from weak REF CURSORs can be associated with any query at runtime. A REF CURSOR declaration with a RETURN clause defines a *strong* REF CURSOR. A cursor variable based on a strong REF CURSOR can be associated with queries whose result sets match the number and datatype of the record structure after the RETURN at runtime.

To use cursor variables, you must first create a REF CURSOR type, then declare a cursor variable based on that type.

The following example shows the use of both weak and strong REF CURSORs:

```
DECLARE
    -- Create a cursor type based on the company table.
    TYPE company_curtype IS REF CURSOR
        RETURN companies%ROWTYPE;

    -- Create the variable based on the REF CURSOR.
    company_cur company_curtype;

    -- And now the weak, general approach.
    TYPE any_curtype IS REF CURSOR;
    generic_curvar any_curtype;
```

The syntax to OPEN a cursor variable is:

```
OPEN cursor_name FOR SELECT_statement;
```

You can FETCH and CLOSE a cursor variable using the same syntax as for explicit cursors.

There are several restrictions on cursor variables:

- You cannot declare package-level cursor variables because they do not have a persistent state. (You can declare them in packaged procedures and functions, however.)
- You cannot assign NULLs to a cursor variable nor can you use comparison operators to test for equality, inequality, or nullity.
- Neither database columns nor collections can store cursor variables.
- You cannot use remote procedure calls (RPCs) to pass cursor variables from one server to another.

Cursor Expressions

A cursor expression is a cursor that is used as a column expression in the SELECT list of an explicit cursor. The syntax for a cursor expression is:

```
CURSOR (subquery)
```

Cursor expressions can reduce the amount of redundant data returned to a calling program over techniques that involve joining the tables together. The cursor expression is opened automatically when the parent row is fetched. Cursor expressions can be nested as well. These nested cursors are closed when one of the following occurs:

- The nested cursor is explicitly closed by the program.
- The parent cursor is closed.
- The parent cursor is re-executed.
- An exception is raised during the fetch of the parent row.

An example of a cursor expression follows:

```
DECLARE
   TYPE refcursor IS REF CURSOR;
   CURSOR order_cur IS
      SELECT o.order_date ,o.order_status
```

```
              ,CURSOR(SELECT p.translated_name
                           ,i.unit_price
                           ,i.quantity
                      FROM oe.order_items i
                          ,oe.product_descriptions p
                     WHERE i.product_id = p.product_id
                       AND i.order_id = o.order_id)
          FROM oe.orders o
          WHERE order_date BETWEEN TO_DATE('01-Jan-03')
                              AND TO_DATE('31-Jan-03');
    odate    oe.orders.order_date%TYPE;
    ostatus  oe.orders.order_status%TYPE;
    od_cur   refcursor;
    tname    oe.product_descriptions.translated_name%TYPE;
    price    oe.order_items.unit_price%TYPE;
    qty      oe.order_items.quantity%TYPE;
BEGIN
    OPEN order_cur;
    LOOP
       FETCH order_cur INTO odate, ostatus, od_cur;
       EXIT WHEN order_cur%NOTFOUND;
       LOOP
          FETCH od_cur INTO tname, price, qty;
          EXIT WHEN od_cur%NOTFOUND;
          DBMS_OUTPUT.PUT_LINE(odate||','||ostatus
             ||','||tname||','||price||','||qty);
       END LOOP;
    END LOOP;
    CLOSE order_cur;
END;
```

Exception Handling

PL/SQL allows developers to raise and handle errors (exceptions) in a very flexible and powerful way. Each PL/SQL block can have its own exception section in which exceptions can be trapped and handled (resolved or passed on to the enclosing block). When an exception occurs (is raised) in a PL/SQL block, its execution section immediately terminates. Control is passed to the exception section. Every exception in PL/SQL has an error number and error message; some exceptions also have names.

Declaring Exceptions

Some exceptions have been predefined by Oracle in the STANDARD package or other built-in packages, such as UTL_FILE. See the following table for some of the most common predefined exceptions. You also can declare your own exceptions as follows:

```
DECLARE
    exception_name EXCEPTION;
```

Error	Named exception
ORA-00001	DUP_VAL_ON_INDEX
ORA-00051	TIMEOUT_ON_RESOURCE
ORA-00061	TRANSACTION_BACKED_ OUT
ORA-01001	INVALID_CURSOR
ORA-01012	NOT_LOGGED_ON
ORA-01017	LOGIN_DENIED
ORA-01403	NO_DATA_FOUND
ORA-01410	SYS_INVALID_ROWID
ORA-01422	TOO_MANY_ROWS
ORA-01476	ZERO_DIVIDE
ORA-01725	USERENV_COMMMITSCN_ ERROR
ORA-01722	INVALID_NUMBER
ORA-06500	STORAGE_ERROR
ORA-06501	PROGRAM_ERROR
ORA-06502	VALUE_ERROR
ORA-06504	ROWTYPE_MISMATCH
ORA-06511	CURSOR_ALREADY_OPEN
ORA-06530	ACCESS_INTO_NULL
ORA-06531	COLLECTION_IS_NULL
ORA-06532	SUBSCRIPT_OUTSIDE_LIMIT
ORA-06533	SUBSCRIPT_BEYOND_COUNT

Error	Named exception
ORA-06548	NO_DATA_NEEDED
ORA-06592	CASE_NOT_FOUND
ORA-30625	SELF_IS_NULL

An exception can be declared only once in a block, but nested blocks can declare an exception with the same name as an outer block. If this multiple declaration occurs, scope takes precedence over name when handling the exception. The inner block's declaration takes precedence over a global declaration.

When you declare your own exception, you must RAISE it explicitly. All declared exceptions have an error code of 1 and the error message "User-defined exception," unless you use the EXCEPTION_INIT pragma.

You can associate an error number with a declared exception with the PRAGMA EXCEPTION_INIT statement using the following syntax:

```
DECLARE
    exception_name EXCEPTION;
    PRAGMA EXCEPTION_INIT (exception_name, error_number);
```

where *error_number* is a literal value (variable references are not allowed). This number can be an Oracle error, such as –955 (object exists), or an error in the user-definable range 20000 to –20999. For example, to execute the dynamic SQL in the variable sql_stmt, ignoring any ORA-00955 errors, run the following:

```
DECLARE
  ObjectExists EXCEPTION;
  PRAGMA EXCEPTION_INIT(ObjectExists,-955);
  sql_stmt VARCHAR2(100) := 'CREATE TABLE mydual AS SELECT
      * FROM dual';
BEGIN
  EXECUTE IMMEDIATE sql_stmt;
-- Ignore ORA-955 errors (object already exists)
EXCEPTION WHEN ObjectExists THEN NULL;
END;
```

Raising Exceptions

An exception can be raised in three ways:

- By the PL/SQL runtime engine
- By an explicit RAISE statement in your code
- By a call to the built-in function RAISE_APPLICATION_ ERROR

The syntax for the RAISE statement is:

```
RAISE exception_name;
```

where *exception_name* is the name of an exception that you have declared, or an exception that is declared in the STANDARD package. If you use the RAISE statement inside an exception handler, you can omit the exception name to re-raise the current exception:

```
RAISE;
```

This syntax is not valid outside the exception section.

The RAISE_APPLICATION_ERROR built-in function has the following header:

```
RAISE_APPLICATION_ERROR (
    num BINARY_INTEGER,
    msg VARCHAR2,
    keeperrorstack BOOLEAN DEFAULT FALSE);
```

where *num* is the error number (an integer between –20999 and -20000), *msg* is the associated error message, and *keep_ errorstack* controls whether any previous contents of the error stack are preserved.

Starting with Oracle Database 10*g* Release 2, you can use the built-in function DBMS_UTILITY.FORMAT_ERROR_ BACKTRACE to assist in identifying where in the call stack an error occurred. Prior to Oracle Database 10*g* Release 2, the only way to capture the full error stack and determine the line number on which an error was raised was to let the exception go unhandled.

Scope

The *scope* of an exception section is that portion of the code that is "covered" by the exception section. An exception handler will handle, or attempt to handle, only those exceptions that are raised in the executable section of the PL/SQL block. Exceptions raised in the declaration or exception sections are passed to the outer block automatically. Any line or set of PL/SQL code can be placed inside its own block and given its own exception section. This allows you to limit the propagation of an exception.

Propagation

Exceptions raised in a PL/SQL block propagate to an outer block if they are unhandled or re-raised in the exception section. When an exception occurs, PL/SQL looks for an exception handler that checks for the exception (or is the WHEN OTHERS clause) in the current block. If a match is not found, PL/SQL propagates the exception to the enclosing block or calling program. This propagation continues until the exception is handled or propagated out of the outermost block, back to the calling program. In this case, the exception is "unhandled" and (1) stops the calling program, and (2) causes an automatic rollback of any outstanding transactions.

Once an exception is handled, it will not propagate upward. If you want to trap an exception, display a meaningful error message, and have the exception propagate upward as an error, you must re-raise the exception. The RAISE statement can reraise the current exception or raise a new exception, as shown here:

```
PROCEDURE delete_dept(deptno_in IN NUMBER)
IS
   still_have_employees EXCEPTION;
   PRAGMA EXCEPTION_INIT(still_have_employees, -2292);
BEGIN
   DELETE FROM dept
    WHERE deptno = deptno_in;
```

```
EXCEPTION
   WHEN still_have_employees
   THEN
      DBMS_OUTPUT.PUT_LINE
         ('Please delete employees in dept first');
      ROLLBACK;
      RAISE;  --Re-raise the current exception.
END;
```

WHEN OTHERS clause

Use the WHEN OTHERS clause in the exception handler as
a catch-all to trap any exceptions that are not handled by
specific WHEN clauses in the exception section. If present,
this clause must be the last exception handler in the excep-
tion section. Specify this clause as follows:

```
EXCEPTION
   WHEN OTHERS
   THEN
      ...
```

SQLCODE, SQLERRM, and DBMS_UTILITY.FORMAT_ CALL_STACK

SQLCODE, SQLERRM, and DBMS_UTILITY.FORMAT_
CALL_STACK are built-in functions and procedures that
provide error code and message information for recent
exceptions. Use these programs inside the exception sec-
tion's WHEN OTHERS clause to obtain information about
the current exception.

Oracle Corporation recommends that you not use
SQLERRM, because under some circumstances that func-
tion may truncate the error message string. Instead, use the
FORMAT_CALL_STACK procedure, like this:

```
CREATE TABLE err_test
   (widget_name   VARCHAR2(100)
   ,widget_count  NUMBER
   ,CONSTRAINT no_small_numbers CHECK
      (widget_count > 1000));
BEGIN
   INSERT INTO err_test (widget_name, widget_count)
   VALUES ('Athena',2);
```

```
EXCEPTION
   WHEN OTHERS THEN
      IF SQLCODE = -2290
         AND DBMS_UTILITY.FORMAT_ERROR_STACK LIKE
            '%NO_SMALL_NUMBERS%'
      THEN
         DBMS_OUTPUT.PUT_LINE ( 'Widget_count is too
            small.' );
      ELSE
         DBMS_OUTPUT.PUT_LINE('Exception not handled '
            ||'SQLcode='||SQLCODE);
         DBMS_OUTPUT.PUT_LINE(DBMS_UTILITY.FORMAT_CALL_
            STACK);
      END IF;
END;
```

This produces the following output:

```
Widget_count is too small.
```

Starting with Oracle Database 10g Release 1, the DBMS_UTILITY.FORMAT_ERROR_BACKTRACE function can be used to display the full call stack, even if this procedure is called from an exception handler in an outer scope.

Exceptions and DML

When an exception is raised in a PL/SQL block, it does *not* roll back your current transaction, even if the block itself issued an INSERT, UPDATE, or DELETE. You must issue your own ROLLBACK statement if you want to clean up your transaction as a result of the exception.

If your exception goes unhandled (propagates out of the outermost block), however, most host environments, including SQL*Plus, will then force an automatic, unqualified rollback of any outstanding changes in your session.

Records in PL/SQL

A PL/SQL record is a data structure composed of multiple pieces of information called *fields*. To use a record, you must first define it and declare a variable of this type. There

---

are three types of records: table-based, cursor-based, and programmer-defined.

Declaring Records

Define and declare records either in the declaration section of a PL/SQL block or globally, via a package specification.

You do not have to explicitly define table-based or cursor-based records, as they are implicitly defined with the same structure as a table or a cursor. Variables of these types are declared via the %ROWTYPE attribute. The record's fields correspond to the table's columns or the columns in the SELECT list. For example:

```
DECLARE
    -- Declare table-based record for company table.
    comp_rec   company%ROWTYPE

    CURSOR comp_summary_cur IS
       SELECT c.company_id,SUM(s.gross_sales) gross
         FROM company c ,sales s
        WHERE c.company_id = s.company_id;

    -- Declare a cursor-based record.
    comp_summary_rec   comp_summary_cur%ROWTYPE;
```

Programmer-defined records must be explicitly defined with the TYPE statement in the PL/SQL declaration section or in a package specification. Variables of this type then can be declared as shown here:

```
DECLARE
    TYPE name_rectype IS RECORD(
       prefix       VARCHAR2(15)
       ,first_name  VARCHAR2(30)
       ,middle_name VARCHAR2(30)
       ,sur_name    VARCHAR2(30)
       ,suffix      VARCHAR2(10) );

    TYPE employee_rectype IS RECORD (
       emp_id       NUMBER(10) NOT NULL
       ,mgr_id      NUMBER(10)
       ,dept_no     dept.deptno%TYPE
```

```
     ,title      VARCHAR2(20)
     ,name       name_rectype
     ,hire_date  DATE := SYSDATE
     ,fresh_out  BOOLEAN );

   -- Declare a variable of this type.
   new_emp_rec employee_rectype;
BEGIN
```

Referencing Fields of Records

Individual fields are referenced via dot notation:

```
record_name.field_name
```

For example:

```
employee.first_name
```

Individual fields within a record can be read from or written to. They can appear on either the left or right side of the assignment operator:

```
BEGIN
   insurance_start_date :=
      new_emp_rec.hire_date + 30;
   new_emp_rec.fresh_out := FALSE;
   ...
```

Assigning Records

An entire record can be assigned to another record of the same type, but one record cannot be compared to another record via Boolean operators. This is a valid assignment:

```
shipto_address_rec := customer_address_rec
```

This is not a valid comparison:

```
IF shipto_address_rec = customer_address_rec
   -- illegal
THEN
   ...
END IF;
```

The individual fields of the records need to be compared instead.

Values can be assigned to records or to the fields within a record in four different ways:

- You can use the assignment operator to assign a value to a field:

  ```
  new_emp_rec.hire_date := SYSDATE;
  ```

- You can SELECT INTO a whole record or the individual fields:

  ```
  SELECT emp_id,dept,title,hire_date,college_recruit
    INTO new_emp_rec
    FROM emp
   WHERE surname = 'LI'
  ```

- You can FETCH INTO a whole record or the individual fields:

  ```
  FETCH emp_cur INTO new_emp_rec;
  FETCH emp_cur
   INTO new_emp_rec.emp_id, new_emp_rec.name;
  ```

- You can assign all the fields of one record variable to another record variable of the same type:

  ```
  IF rehire THEN
    new_emp_rec := former_emp_rec;
  ENDIF;
  ```

  This aggregate assignment technique works only for records declared with the same TYPE statement.

Records and DML

You insert into or update a database table using a %ROWTYPE record without having to specify each field individually in the following ways:

- Insert into a database table, using a %ROWTYPE record and the VALUES keyword:

  ```
  DECLARE
     emp_rec  emp%ROWTYPE;
  BEGIN
     SELECT employees_seq.NEXTVAL
       INTO emp_rec.empno FROM dual;

     INSERT INTO emp VALUES (emp_rec);
  END;
  ```

- Update a database table using a %ROWTYPE record and
  the SET ROW keywords:

```
FOR emp_rec IN emp_cur
LOOP
   change_record_values(emp_rec);

   UPDATE emp SET ROW = emp_rec
    WHERE empno = emp_rec.empno;
END LOOP;
```

While these techniques allow you to write more elegant code
to interact with a database, you cannot use %ROWTYPE
records as bind variables in dynamic SQL.

Nested Records

Nested records are records contained in fields that are
records themselves. Nesting records is a powerful way to
normalize data structures and hide complexity within PL/
SQL programs. For example:

```
DECLARE
   -- Define a record.
   TYPE phone_rectype IS RECORD (
      area_code  VARCHAR2(3),
      exchange   VARCHAR2(3),
      phn_number VARCHAR2(4),
      extension  VARCHAR2(4));

   -- Define a record composed of records.
   TYPE contact_rectype IS RECORD (
      day_phone#  phone_rectype,
      eve_phone#  phone_rectype,
      cell_phone# phone_rectype);

-- Declare a variable for the nested record.
 auth_rep_info_rec contact_rectype;
BEGIN
```

Collections in PL/SQL

There are three types of collections in PL/SQL: associative arrays (formerly known as index-by tables or PL/SQL tables), nested tables, and VARRAYs.

Associative arrays

Single-dimension, unbounded collections of homogeneous elements available only in PL/SQL, not in the Oracle database. Associative arrays are initially sparse; they have nonconsecutive subscripts. There are two types of associative arrays: INDEX BY BINARY_INTEGER, which allows you to associate a value with a BINARY_INTEGER, and INDEX BY VARCHAR2, which allows you to associate a value with a text string.

Nested tables

Single-dimension, unbounded collections of homogeneous elements available in both PL/SQL and the Oracle database as a column of a table. Nested tables initially are dense (they have consecutive subscripts), but they can become sparse through deletions.

VARRAYs

Variable-size arrays. Single-dimension, bounded collections of homogeneous elements available in both PL/SQL and the Oracle database. VARRAYs are never sparse. Unlike nested tables, their element order is preserved when you store and retrieve them from the database.

The following table compares these similar collection types:

Characteristic	Associative array	Nested table	VARRAY
Dimensionality	Single	Single	Single
Usable in SQL?	No	Yes	Yes
Usable as a column datatype in a table?	No	Yes; data stored "out of line" (in a separate table)	Yes; data typically stored "inline" (in the same table)

Characteristic	Associative array	Nested table	VARRAY
Uninitialized state	Empty (cannot be NULL); elements are undefined	Atomically null; illegal to reference elements	Atomically null; illegal to reference elements
Initialization	Automatic, when declared	Via constructor, fetch, assignment	Via constructor, fetch, assignment
In PL/SQL, elements referenced by	BINARY_INTEGER (−2,147,483,647 .. 2,147,483,647) or character string (VARCHAR2); maximum length of VARCHAR2 is 30, minimum length is 1	Positive integer between 1 and 2,147,483,647 elements cannot be referenced unless they have been initialized via the constructor or with the EXTEND function	Positive integer between 1 and 2,147,483,647; elements cannot be referenced unless they have been initialized via the constructor or with the EXTEND function
Sparse?	Yes	Initially no; after deletions, yes	No
Bounded?	No	Can be extended	Yes
Growing the number of elements in the collection	Assign a value to the element using a new subscript	Elements are added via the constructor or later via the EXTEND method	Elements are added via the constructor or later via the EXTEND method; however, you cannot EXTEND past the upper bound
Shrinking the size of the collection	Automatic	TRIM function	TRIM function
Can be compared for equality?	No	Yes (in Oracle Database 10g and later) No (in Oracle9i Database Release 2 and earlier)	No
Elements retain ordinal position and subscript when stored and retrieved from the database	N/A; can't be stored in database	No	Yes

Declaring a Collection

Collections are implemented as TYPEs. As with any programmer-defined type, you must first define the type; then you can declare instances of that type. The TYPE definition can be stored in the database or declared in the PL/SQL program. Each instance of the TYPE is a collection.

The syntax for declaring an associative array is:

```
TYPE type_name IS TABLE OF element_type [NOT NULL]
   INDEX BY {BINARY_INTEGER | VARCHAR2 (size_limit)};
```

The syntax for a nested table is:

```
[CREATE [OR REPLACE]] TYPE type_name { IS | AS } TABLE OF
   element_type [NOT NULL];
```

The syntax for a VARRAY is:

```
[CREATE [OR REPLACE]] TYPE type_name { IS | AS } VARRAY |
   VARYING ARRAY (max_elements) OF element_type
   [NOT NULL];
```

The CREATE keyword defines the statement to be DDL and indicates that this type will exist in the database. The optional OR REPLACE keywords are used to rebuild an existing type, preserving the privileges. *type_name* is any valid identifier that will be used later to declare the collection. *max_elements* is the maximum size of the VARRAY. *element_type* is the type of the collection's elements. All elements are of a single type, which can be most scalar datatypes, an object type, or a REF object type. If the elements are objects, the object type itself cannot have an attribute that is a collection. Explicitly disallowed collection datatypes are BOOLEAN, NCHAR, NCLOB, NVARCHAR2, REF CURSOR, TABLE, and VARRAY.

NOT NULL indicates that a collection of this type cannot have any null elements. However, the collection can be atomically null (uninitialized).

Initializing a Collection

Initializing an associative array is trivial—simply declaring it also initializes it. Initializing a nested table or a VARRAY can be done in any of three ways: explicitly with a constructor, implicitly with a fetch from the database, or implicitly with a direct assignment of another collection variable.

The constructor is a built-in function with the same name as the collection. It constructs the collection from the elements passed to it. The following example shows how you can create a nested table of colors and explicitly initialize it to three elements with a constructor:

```
DECLARE
    TYPE colors_tab_t IS TABLE OF VARCHAR2(30);
    colors_tab colors_tab_t :=
        colors_tab_t('RED','GREEN','BLUE');
BEGIN
```

The next example shows how you can create the nested table of colors and implicitly initialize it with a fetch from the database:

```
-- Create the nested table to exist in the database.
CREATE TYPE colors_tab_t IS TABLE OF VARCHAR2(32);

-- Create table with nested table type as column.
CREATE TABLE color_models
(model_type    VARCHAR2(12)
,colors        color_tab_t)
NESTED TABLE colors STORE AS
    color_model_colors_tab;

-- Add some data to the table.
INSERT INTO color_models
    VALUES('RGB',color_tab_t('RED','GREEN','BLUE'));
INSERT INTO color_models
    VALUES('CYMK',color_tab_t('CYAN','YELLOW',
        'MAGENTA' 'BLACK'));

-- Initialize a collection of colors from the table.
DECLARE
    basic_colors colors_tab_t;
```

```
BEGIN
   SELECT colors INTO basic_colors
     FROM color_models
    WHERE model_type = 'RGB';
...
END;
```

The third example shows how you can implicitly initialize
the table via an assignment from an existing collection:

```
DECLARE
   basic_colors Color_tab_t :=
      Color_tab_t ('RED','GREEN','BLUE');
   my_colors Color_tab_t;
BEGIN
   my_colors := basic_colors;
   my_colors(2) := 'MUSTARD';
```

Adding and Removing Elements

Elements in an associative array can be added simply by ref-
erencing new subscripts. To add elements to nested tables or
VARRAYs, you must first enlarge the collection with the
EXTEND function, and then you can assign a value to a new
element using one of the methods described in the previous
section.

Use the DELETE function to remove an element in a nested
table regardless of its position. The TRIM function also can
be used to remove elements, but only from the end of a col-
lection. To avoid unexpected results, do not use both
DELETE and TRIM on the same collection.

Nested Table Functions

Several collection (multiset) functions can be used to manipu-
late collections. These are summarized in the following table.
Most of these functions were new in Oracle Database 10*g*;
only CAST and MULTISET were available in earlier releases.
Note that COLLECT is valid only in a SQL statement; it can-
not be used, for example, in a PL/SQL assignment.

Function	Return value	Description
=	BOOLEAN	Compares two nested tables and returns TRUE if they have the same named type and cardinality, and if the elements are equal.
<>	BOOLEAN	Compares two nested tables and returns FALSE if they differ in named type, cardinality, or equality of elements.
[NOT] IN ( )	BOOLEAN	Returns TRUE [FALSE] if the nested table to the left of IN exists in the list of nested tables specified in the parentheses.
CARDINALITY(*x*)	NUMBER	Returns the number of elements in VARRAY or nested table *x*. Returns NULL if the collection is atomically NULL (not initialized).
CAST(*k* AS *t*)	TYPE *t*	Changes the datatype of *k* to type *t*; used in conjunction with COLLECT or MULTISET.
COLLECT	NESTED TABLE	Used in conjunction with CAST to map a column to a collection.
MULTISET	NESTED TABLE	Used in conjunction with CAST to map a subquery to a collection.
x MULTISET EXCEPT [DISTINCT] *y*	NESTED TABLE	Performs a MINUS set operation on nested tables *x* and *y*, returning a nested table whose elements are in *x*, but not in *y*. The returned nested table, *x*, and *y* must all be of the same type. The DISTINCT keyword forces the elimination of duplicates from the returned nested table.
x MULTISET INTERSECT [DISTINCT] *y*	NESTED TABLE	Performs an INTERSECT set operation on nested tables *x* and *y*, returning a nested table whose elements are in both *x* and *y*. The returned nested table, *x*, and *y* must all be of the same type. The DISTINCT keyword forces the elimination of duplicates from the returned nested table.
x MULTISET UNION [DISTINCT] *y*	NESTED TABLE	Performs a UNION set operation on nested tables *x* and *y*, returning a nested table whose elements include all those in *x* as well as those in *y*. The returned nested table, *x*, and *y* must all be of the same type. The DISTINCT keyword forces the elimination of duplicates from the returned nested table.
SET(*x*)	NESTED TABLE	Returns nested table *x* without duplicate elements.

Function	Return value	Description
x IS [NOT] A SET	BOOLEAN	Returns TRUE [FALSE] if the nested table *x* is composed of unique elements.
x IS [NOT] EMPTY	BOOLEAN	Returns TRUE [FALSE] if the nested table *x* is empty.
e [NOT] MEMBER [OF] *x*	BOOLEAN	Returns TRUE [FALSE] if an expression *e* is a member of the nested table *x*.
y [NOT] SUBMULTISET [OF] *x*	BOOLEAN	Returns TRUE [FALSE] if the nested table *y* contains only elements that are also in the nested table *x*.

The CAST function works together with the COLLECT and MULTISET functions. MULTISET operates on a subquery. COLLECT operates on a column in a SQL statement:

```
CREATE TYPE email_list_t AS TABLE OF VARCHAR2(64);

-- COLLECT operates on a column
SELECT CAST(COLLECT(cust_email)AS email_list_t)
FROM oe.customers;

-- which is equivalent to
SELECT CAST(MULTISET(SELECT cust_email
                     FROM oe.customers)
            AS email_list_t)
FROM dual;
```

The following provides examples of the other nested table functions, operators, and expressions:

```
DECLARE
  TYPE nested_type IS TABLE OF NUMBER;
  nt1 nested_type := nested_type(1,2,3);
  nt2 nested_type := nested_type(3,2,1);
  nt3 nested_type := nested_type(2,3,1,3);
  nt4 nested_type := nested_type(1,2,4);
  answer nested_type;
BEGIN
  answer := nt1 MULTISET UNION nt4; -- (1,2,3,1,2,4)
  answer := nt1 MULTISET UNION nt3; -- (1,2,3,2,3,1,3)
  answer := nt1 MULTISET UNION DISTINCT nt3; -- (1,2,3)
  answer := nt2 MULTISET INTERSECT nt3; -- (3,2,1)
  answer := nt2 MULTISET INTERSECT DISTINCT nt3;
     -- (3,2,1)
```

```
   answer := nt3 MULTISET EXCEPT nt2; -- (3)
   answer := nt3 MULTISET EXCEPT DISTINCT nt2; -- ()
   answer := SET(nt3); -- (2,3,1)
   IF (nt1 IS A SET) AND (nt3 IS NOT A SET) THEN
      DBMS_OUTPUT.PUT_LINE('nt1 has unique elements');
      DBMS_OUTPUT.PUT_LINE ('but nt3 does not');
   END IF;
   IF (nt3 MULTISET EXCEPT DISTINCT nt2) IS EMPTY THEN
      DBMS_OUTPUT.PUT_LINE('empty set');
   END IF;
   IF 3 MEMBER OF (nt3 MULTISET EXCEPT nt2) THEN
      DBMS_OUTPUT.PUT_LINE('3 is in the answer set');
   END IF;
   IF nt1 SUBMULTISET nt3 THEN
      DBMS_OUTPUT.PUT_LINE('nt1 is a subset of nt3');
   END IF;
   IF SET(nt3) IN (nt1,nt2,nt3)  THEN
     DBMS_OUTPUT.PUT_LINE (
        'expression is IN the list of nested tables');
   END IF;
END;
```

Collection Methods

Several built-in functions (methods) are defined for all collections. These methods are called with dot notation:

collection_name.*method_name*[(*parameters*)]

The methods are listed in the following table:

Collection method	Description
COUNT	A function. Returns the current number of elements in the collection. If a collection is atomically NULL, this method raises an exception. Consider the CARDINALITY( ) function instead.
DELETE [(*i*[,*j*])]	A procedure. Removes element *i* or elements *i* through *j* from a nested table or associative array. When called with no parameters, removes all elements in the collection. Reduces the COUNT if the element is not already DELETEd. Does not apply to VARRAYs.
EXISTS (*i*)	A function. Returns TRUE or FALSE to indicate whether element *i* exists. If the collection is an uninitialized nested table or VARRAY, returns FALSE.

Collection method	Description
EXTEND [(n [, i])]	A procedure. Appends n elements to a collection, initializing them to the value of element i. Both i and n are optional, and n defaults to 1.
FIRST	A function. Returns the lowest index in use. Returns NULL when applied to empty initialized collections.
LAST	A function. Returns the greatest index in use. Returns NULL when applied to empty initialized collections.
LIMIT	A function. Returns the maximum number of allowed elements in a VARRAY. Returns NULL for associative arrays and nested tables.
PRIOR (i)	A function. Returns the index immediately before element i. Returns NULL if i is less than or equal to FIRST.
NEXT (i)	A function. Returns the index immediately after element i. Returns NULL if i is greater than or equal to COUNT.
TRIM [(n)]	A procedure. Removes n elements at the end of the collection with the largest index. n is optional and defaults to 1. If n is NULL, TRIM does nothing. Associative arrays cannot be TRIMmed.

The EXISTS function returns a BOOLEAN, and all other functions and procedures return BINARY_INTEGER except for collections indexed by VARCHAR2, which can return character strings. All parameters are of the BINARY_INTEGER type. Only EXISTS can be used on uninitialized nested tables or VARRAYs. Other methods applied to these atomically null collections will raise the COLLECTION_IS_NULL exception.

DELETE and TRIM both remove elements from a nested table, but TRIM also removes the placeholder, while DELETE does not. This behavior may be confusing because TRIM can remove previously DELETEd elements.

Here are examples of some collection methods in use with an associative array:

```
DECLARE
   TYPE population_type IS
      TABLE OF NUMBER INDEX BY VARCHAR2(64);
```

```
        continent_population population_type;
        howmany NUMBER;
        continent_name VARCHAR2(64);
    BEGIN
        continent_population('Australia') := 30000000;
        -- Create new entry
        continent_population('Antarctica') := 1000;
        -- Replace old value
        continent_population('Antarctica') := 1001;
        continent_name := continent_population.FIRST;
        DBMS_OUTPUT.PUT_LINE (continent_name);
        DBMS_OUTPUT.PUT_LINE (
            continent_population(continent_name));
        continent_name := continent_population.LAST;
        DBMS_OUTPUT.PUT_LINE (continent_name);
        DBMS_OUTPUT.PUT_LINE
            (continent_population(continent_name));
    END;
```

This example produces the following output:

```
    Antarctica
    1001
    Australia
    30000000
```

Here are examples of some collection methods in use with a nested table:

```
    DECLARE
        TYPE colors_tab_t IS TABLE OF VARCHAR2(30);
        my_list colors_tab_t :=
            colors_tab_t('RED','GREEN','BLUE');
        element BINARY_INTEGER;
    BEGIN
        DBMS_OUTPUT.PUT_LINE('my_list has '
            ||my_list.COUNT||' elements');
        my_list.DELETE(2); -- delete element two
        DBMS_OUTPUT.PUT_LINE('my_list has '
            ||my_list.COUNT||' elements');

        FOR element IN my_list.FIRST..my_list.LAST
        LOOP
            IF my_list.EXISTS(element)
            THEN
                DBMS_OUTPUT.PUT_LINE(my_list(element)
                    || ' Prior= '||my_list.PRIOR(element)
```

```
            || ' Next= ' ||my_list.NEXT(element));
        ELSE
          DBMS_OUTPUT.PUT_LINE('Element '|| element
            ||' deleted. Prior=
              '||my_list.PRIOR(element)
            || ' Next= '||my_list.NEXT(element));
        END IF;
    END LOOP;
END;
```

This example produces the following output:

```
my_list has 3 elements
my_list has 2 elements
RED Prior=  Next= 3
Element 2 deleted. Prior= 1 Next= 3
BLUE Prior= 1 Next=
```

Collections and Privileges

As with other TYPEs in the database, you need the EXE-
CUTE privilege on that TYPE to use a collection type cre-
ated by another schema (user account) in the database. You
can use synonyms for user-defined TYPE names.

Nested Collections

Nested collections are collections contained in members that
are collections themselves. Nesting collections is a powerful
way to implement object-oriented programming constructs
within PL/SQL programs. For example:

```
CREATE TYPE books IS TABLE OF VARCHAR2(64);
CREATE TYPE our_books IS TABLE OF books;
```

Bulk Binds

You can use collections to improve the performance of SQL
operations executed iteratively by using *bulk binds*. Bulk
binds reduce the number of context switches between the
PL/SQL engine and the SQL engine. Two PL/SQL language
constructs implement bulk binds: FORALL and BULK COL-
LECT INTO.

The syntax for the FORALL statement is:

```
FORALL bulk_index IN [lower_bound..upper_bound
  | INDICES OF collection_variable[BETWEEN lower_bound AND
      upper_bound]
  | VALUES OF collection_variable ]
  [SAVE EXCEPTIONS]
  sql_statement;
```

bulk_index can be used only in the *sql_statement* and only as a collection index (subscript). When PL/SQL processes this statement, the whole collection—instead of each individual collection element—is sent to the database server for processing. To delete all the accounts in the collection named inactives from the table ledger, do this:

```
FORALL i IN inactives.FIRST..inactives.LAST
   DELETE FROM ledger WHERE acct_no = inactives(i);
```

If nonconsecutive index values result from deletions, you will need to use the INDICES OF syntax to skip over the deleted elements:

```
FORALL i IN INDICES OF inactives
   DELETE FROM ledger WHERE acct_no = inactives(i);
```

If you are interested in the values of a sparse collection of integers instead of the indices, you will need to use the VALUES OF syntax:

```
FORALL i IN VALUES OF inactives_list
   -- inactives_list is a collection of index values from
   -- the inactives table which are earmarked for deletion
   DELETE FROM ledger WHERE acct_no = inactives(i);
```

The INDICES OF and VALUES OF keywords allow you to specify a subset of rows in a driving collection that will be used in the FORALL statement. To match the row numbers in the data collection with the row numbers in the driving collection, use the INDICES OF clause. To match the row numbers in the data collection with the values found in the defined rows of the driving collection, use the VALUES OF clause.

The default is for the database to stop after the first exception encountered. Specify SAVE EXCEPTIONS to indicate that processing should continue after encountering exceptions. The cursor attribute %BULK_EXCEPTIONS stores a collection of records containing the errors. These records have two fields, EXCEPTION_INDEX and EXCEPTION_CODE, which contain the FORALL iteration (during which the exception was raised) as well as the SQLCODE for the exception. If no exceptions are raised, the SQL%BULK_EXCEPTIONS.COUNT method returns 0. For example:

```
DECLARE
  TYPE NameList IS TABLE OF VARCHAR2(32);
  name_tab NameList := NameList('Pribyl'
          ,'Dawes','Feuerstein','Gennick'
          ,'Pribyl','Beresniewicz','Dawes','Dye');
  error_count NUMBER;
  bulk_errors EXCEPTION;
  PRAGMA exception_init(bulk_errors, -24381);
BEGIN
  FORALL indx IN name_tab.FIRST..name_tab.LAST
     SAVE EXCEPTIONS
    INSERT INTO authors (name) VALUES (name_tab(indx));
    -- authors has pk index on name
  EXCEPTION
    WHEN others THEN
      error_count := SQL%BULK_EXCEPTIONS.COUNT;
      DBMS_OUTPUT.PUT_LINE('Number of errors is ' ||
          error_count);
      FOR indx IN 1..error_count LOOP
        DBMS_OUTPUT.PUT_LINE('Error ' || indx || '
            occurred during '||'iteration ' ||
            SQL%BULK_EXCEPTIONS(indx).ERROR_INDEX);
        DBMS_OUTPUT.PUT_LINE('Error is ' ||
          SQLERRM
            (-SQL%BULK_EXCEPTIONS(indx).ERROR_CODE));
      END LOOP;
END;

Number of errors is 2
Error 1 occurred during iteration 5
Error is ORA-00001: unique constraint (.) violated
Error 2 occurred during iteration 7
Error is ORA-00001: unique constraint (.) violated
```

The syntax for the BULK COLLECT INTO clause is:

```
BULK COLLECT INTO collection_name_list;
```

where *collection_name_list* is a comma-delimited list of collections, one for each column in the SELECT. Collections of records cannot be a target of a BULK COLLECT INTO clause. However, the database does support retrieving a set of typed objects and "bulk collecting" them into a collection of objects.

The BULK COLLECT INTO clause can be used in SELECT INTO, FETCH INTO, or RETURNING INTO statements. For example:

```
DECLARE
   TYPE vendor_name_tab IS TABLE OF
      vendors.name%TYPE;
   TYPE vendor_term_tab IS TABLE OF
      vendors.terms%TYPE;
   v_names vendor_name_tab;
   v_terms vendor_term_tab;
BEGIN
   SELECT name, terms
     BULK COLLECT INTO v_names, v_terms
     FROM vendors
    WHERE terms < 30;
   ...
END;
```

The next function deletes products in an input list of categories, and the SQL RETURNING clause returns a list of deleted products:

```
FUNCTION cascade_category_delete (categorylist clist_t)
RETURN prodlist_t
IS
   prodlist prodlist_t;
BEGIN
   FORALL aprod IN categorylist.FIRST..categorylist.LAST
      DELETE FROM product WHERE product_id IN
         categorylist(aprod)
         RETURNING product_id BULK COLLECT INTO prodlist;
   RETURN prodlist;
END;
```

You can use the SQL%BULK_ROWCOUNT cursor attribute for bulk bind operations. It is like an associative array containing the number of rows affected by the executions of the bulk bound statements. The *n*th element of SQL%BULK_ROWCOUNT contains the number of rows affected by the *n*th execution of the SQL statement. For example:

```
FORALL i IN inactives.FIRST..inactives.LAST
   DELETE FROM ledger WHERE acct_no = inactives(i);
FOR counter IN inactives.FIRST..inactives.LAST
LOOP
   IF SQL%BULK_ROWCOUNT(counter) = 0
   THEN
      DBMS_OUTPUT.PUT_LINE('No rows deleted for '||
         counter);
   END IF;
END LOOP;
```

You cannot pass SQL%BULK_ROWCOUNT as a parameter to another program or use an aggregate assignment to another collection. %ROWCOUNT contains a summation of all %BULK_ROWCOUNT elements. %FOUND and %NOTFOUND reflect only the last execution of the SQL statement.

Built-in Functions and Packages

Oracle Corporation supplies many built-in functions and packages. The following sections describe those used most often by PL/SQL developers.

Built-in Functions

The Oracle database provides dozens of built-in functions. Although most of these functions are available to both SQL and PLSQL, there are some notable exceptions. The DECODE function, for example, is not available to PL/SQL except within SQL statements included in your PL/SQL programs. The *Oracle Database SQL Reference* contains implementation details for the many functions defined to PL/SQL

with the package STANDARD. You can view this package specification within the file *stdspec.sql* located in the *ORACLE_HOME/rdbms/admin* directory on the database server.

Conversion functions

Built-in function	Description
ASCIISTR(*string*)	Converts *string* in any character set to the ASCII version of *string* in the database character set.
CAST(*expression* AS *datatype*)	Converts *expression* to type *datatype*. (Use as a powerful substitute for TO_DATE.)
CHARTOROWID(*string*)	Converts *string* to a ROWID datatype.
CONVERT(*string, destination_character_ set, source_character_set*)	Converts *string* from the source character set to the destination character set. (The default source character set is the database character set.)
FROM_TZ(*timestamp_value, time_zone*)	Adds time zone information to a TIMESTAMP value (converting it to a TIMESTAMP WITH TIME ZONE value).
HEXTORAW(*string*)	Converts *string* containing hexadecimal characters to its raw equivalent.
MULTISET	Maps a database table to a collection.
NUMTODSINTERVAL(*n, interval_unit*)	Converts numeric expression *n* to an INTERVAL DAY TO SECOND literal; *interval_unit* can be DAY, HOUR, MINUTE, or SECOND.
NUMTOYMINTERVAL(*n ,interval_unit*)	Converts numeric expression *n* to an INTERVAL YEAR TO MONTH literal; *interval_unit* can be YEAR or MONTH.
RAWTOHEX(*raw*)	Converts *raw* value to its hexadecimal equivalent.
REFTOHEX(*ref*)	Converts *ref* expression into a string containing its hexadecimal equivalent.
ROWIDTOCHAR(*rowid*)	Converts *rowid* to a VARCHAR2(18) string equivalent.
ROWIDTONCHAR(*rowid*)	Converts *rowid* to an NVARCHAR2(18) string equivalent.

Built-in function	Description
TABLE	Maps a collection to a database table (inverse of MULTISET).
THE	Maps a single column value in a single row into a virtual database table.
TO_BINARY_FLOAT(*expression* [,*fmt*])	Converts number or string *expression* to a BINARY_FLOAT; optionally use format model *fmt*.
TO_BINARY_DOUBLE(*expression* [,*fmt*])	Converts number or string *expression* to a BINARY_DOUBLE; optionally use format model *fmt*.
TO_CHAR, TO_NCHAR(*expression* [,*fmt*])	Converts *expression* to a string (VARCHAR2 or NVARCHAR2, respectively); optionally use format model *fmt*.
TO_CLOB, TO_NCLOB(*c*)	Converts *c* from a VARCHAR2, NVARCHAR2, or NCLOB value to a CLOB (or NCLOB).
TO_DATE(*expression* [,*fmt*])	Converts string *expression* to a DATE datatype; optionally use format model *fmt*.
TO_DSINTERVAL(*string*)	Converts character *string* of a CHAR, VARCHAR2, NCHAR, or NVARCHAR2 datatype to an INTERVAL DAY TO SECOND type.
TO_LOB(*c*)	Converts *c* from a LONG or LONG RAW to a LOB.
TO_MULTI_BYTE(*string*)	Where possible, converts single-byte characters in the input *string* to their multibyte equivalents.
TO_NUMBER(*expression* [,*fmt*])	Converts string or numeric (such as a BINARY_FLOAT) *expression* to a NUMBER; optionally use format model *fmt*.
TO_RAW(*b*)	Converts *b* from a BLOB to a RAW.
TO_SINGLE_BYTE(*string*)	Converts multibyte characters in *string* to their corresponding single-byte characters.
TO_TIMESTAMP(*expression* [,*fmt*])	Converts string *expression* to a value of type TIMESTAMP; optionally use format model *fmt*.

Built-in function	Description
TO_TIMESTAMP_TZ(*expression* [,*fmt*])	Converts string *expression* to a value of type TIMESTAMP WITH TIMEZONE; optionally use format model *fmt*.
TO_YMINTERVAL(*string*)	Converts character *string* of a CHAR, VARCHAR2, NCHAR, or NVARCHAR2 datatype to an INTERVAL YEAR TO MONTH type.
TRANSLATE ... USING(*string* USING CHAR_CS)	Converts *string* between the database character set and the national character set. Used for ANSI compatibility; mimics TO_CHAR or TO_NCHAR functionality.
UNISTR(*string*)	Translates *string* containing Unicode encoding values (e.g., x00e5) to a Unicode string literal in the database Unicode character set.

String functions

Built-in function	Description
ASCII(*single_character*)	Returns the NUMBER code representing the specified character in the database character set.
ASCIISTR(*string*)	Takes a *string* in any character set and converts it into a string of ASCII characters. Any non-ASCII characters are represented using \XXXX Unicode notation.
CHR(*code_location*)	Returns a VARCHAR2 character (length 1) that corresponds to the location in the collating sequence provided as a parameter (opposite of ASCII). A variation of CHR is useful when working with national character set data.
CHR(*code_location* USING NCHAR_CS)	Returns an NVARCHAR2 character from the national character set.
COMPOSE(*string*)	Takes a Unicode *string* as input and returns that string in its fully normalized form.
CONCAT(*string1, string2*)	Appends *string2* to the end of *string1*.

Built-in function	Description
CONVERT(*string, target_char_set*)	Converts a *string* from the database character set to the specified target character set. You may optionally specify a source character set: CONVERT(*string1, target_char_set, source_character_set*).
DECOMPOSE(*string1* [CANONICAL])	Takes a Unicode *string* as input and returns that string with any precomposed characters decomposed into their separate elements (the opposite of COMPOSE). CANONICAL optionally gives a result that may be reversed using COMPOSE.
GREATEST(*string1, string2, ...*)	Takes one or more *string*s as input and returns the string that would come last (i.e., sorts highest) if the inputs were sorted in ascending order. (LEAST is the opposite of GREATEST.)
INITCAP(*string*)	Reformats the case of the *string* argument, setting the first letter of each word to uppercase and the remainder of the letters to lowercase. A word is a set of characters separated by a space or nonalphanumeric character (such as # or _). For example, INITCAP('this is lower') gives 'This Is Lower'.
INSTR(*string1, string2*[[, *start_position*], *nth*])	Returns the position at which *string2* is found within *string1*; otherwise, returns 0. *start_position* defines the starting position and defaults to 1 if not present. With a negative *start_position*, searching begins at the end of *string1* and works backward. *nth* defines the ordinal occurrence (1st, 2nd, 3rd, etc.) of *string2* in *string1*, and defaults to 1 if not present.
LEAST(*string1, string2, ...*)	Takes one or more *string*s as input and returns the string that would come first (i.e., the least) if the inputs were sorted in ascending order. (GREATEST is the opposite of LEAST.)

Built-in function	Description
LENGTH(*string*)	Returns the number of characters in a *string*. The variations LENGTHB, LENGTHC, LENGTH2, and LENGTH4 return the number of bytes, the number of Unicode characters, the number of USC2 code points, and the number of USC4 code points, respectively. LENGTH returns NULL when passed a NULL, and zero when passed a zero length (but non-NULL) CLOB.
LOWER(*string*)	Converts all letters in the specified *string* to lowercase (the opposite of UPPER).
LPAD(*string, padded_length* [,*pad_string*])	Returns the value from *string*, but padded on the left with enough *pad_string* characters to make the result *padded_length* characters long. *pad_string* defaults to a space if not present.
LTRIM(*string* [,*trim_string*])	Removes, or trims, any characters found in *trim_string* from the leading edge of *string1*. *trim_string* defaults to a space if not present. (See also TRIM [ISO standard] and RTRIM.)
NCHR(*code_location*)	Returns an NVARCHAR2 character (length 1) that corresponds to the location in the national character set collating sequence specified by *code_location*. (Provides the same functionality as the CHR function's USING NCHAR_CS clause.)
NLS_INITCAP(*string*)	Returns a version of *string* (which should be of type NVARCHAR2 or NCHAR), setting the first letter of each word to uppercase and the remainder to lowercase. The return value is a VARCHAR2. A word is a set of characters separated by a space or nonalphanumeric character.
NLS_INITCAP(*string*, 'NLS_SORT= *sort_sequence_name*')	You may specify a linguistic sorting sequence that affects the definition of "first letter," as above. For *sort_sequence_name*, specify a linguistic sort name as described in the *Oracle Database Globalization Support Guide*, Appendix A, (under "Linguistic Sorts").

Built-in function	Description
NLS_LOWER(*string*) and NLS_LOWER(*string*, 'NLS_SORT=*sort_sequence_name*')	Lowercases a *string* in accordance with language-specific rules. (See NLS_INITCAP for how NLS_SORT can affect the results.)
NLS_UPPER(*string*) and NLS_UPPER(*string*, 'NLS_SORT=*sort_sequence_name*')	Uppercases a *string* in accordance with language-specific rules. (See NLS_INITCAP for how NLS_SORT can affect the results.)
NLSSORT(*string*) and NLSSORT(*string*, 'NLS_SORT= *sort_sequence_name* ')	Returns a *string* of bytes that can be used to sort a string value in accordance with language-specific rules. The string returned is of the RAW datatype.
REGEXP_INSTR, REGEXP_LIKE, REGEXP_REPLACE, REGEXP_SUBSTR	See the following section, "Built-in Regular Expression Functions," for descriptions.
REPLACE(*string*, *match_string*, *replace_string*)	Returns a *string* in which all occurrences of *match_string* in *string* are replaced by *replace_string*. Use REPLACE to search for a pattern of characters and then change all instances of that pattern in a single function call.
RPAD(*string*, *padded_length* [,*pad_string*])	Returns *string* padded on the right with enough *pad_string* occurrences to make the result *padded_length* characters long. *pad_string* defaults to a space.
RTRIM(*string* [,*trim_string*])	Removes, or trims, any *trim_string* characters from the right, or trailing edge, of *string*. (See also TRIM [ISO standard] and LTRIM.) *trim_string* defaults to a space.
SOUNDEX(*string*)	Returns a character *string* that is the "phonetic representation" of the argument.
SUBSTR(*string*, *start*, [*length*])	Returns a substring from *string*, beginning with the character at position *start* and going for *length* characters. If *start* is negative, the beginning position is counted from the end of the string rather than the beginning. *length* defaults to the remainder of *string*.
TO_CHAR(*national_character_data*)	Converts data in the national character set to its equivalent representation in the database character set. (See also TO_NCHAR.) You can also use TO_CHAR to convert date and time values, as well as numbers, into human-readable form.

Built-in function	Description
TO_MULTI_BYTE(*string*)	Translates single-byte characters to their multibyte equivalents (the opposite of TO_SINGLE_BYTE).
TO_NCHAR(*database_character_data*)	Converts data in the database character set to its equivalent representation in the national character set. (See also TO_CHAR and TRANSLATE…USING.)
TO_SINGLE_BYTE(*string*)	Translates multibyte characters to their single-byte equivalents (the opposite of TO_MULTI_BYTE).
TRANSLATE (*string*, *search_set*, *replace_set*)	Replaces every instance in *string* of a character from *search_set* with the corresponding character from *replace_set*.
TRANSLATE(*text* USING CHAR_CS) and TRANSLATE(*text* USING NCHAR_CS)	Translates character data to either the database character set (CHAR_CS) or the national character set (NCHAR_CS). The output datatype will be either VARCHAR2 or NVARCHAR2, depending on whether you are converting to the database or the national character set, respectively.
TRIM ([LEADING | TRAILING | BOTH] *trim_character* FROM *string*)	Returns a version of *string* that omits any leading and trailing spaces. The optional keywords LEADING FROM, TRAILING FROM, and BOTH FROM cause the trimming of only leading, trailing, or both leading and trailing *trim_characters*. *trim_character* defaults to a space.
UNISTR(*string*)	Returns *string* converted into Unicode (the opposite of ASCISTR). You can represent nonprintable characters in the input *string* using \XXXX Unicode notation.
UPPER(*string*)	Returns a version of *string* with all letters made uppercase.

Numeric functions

Built-in function	Description
ABS(*n*)	Returns the absolute value of *n*.
ACOS(*n*)	Returns the inverse cosine of *n*, where *n* must be between π and 1. The returned value is between 0 and π.

Built-in function	Description
ASIN(*n*)	Returns the inverse sine, where *n* must be between −1 and 1. The returned value is between −π/2 and π/2.
ATAN(*n*)	Returns the inverse tangent, where the number *n* must be between −infinity and infinity. The returned value is between −π/2 and π/2.
ATAN2(*n*, *m*)	Returns the inverse tangent of *n/m*, where the numbers *n* and *m* must be between −infinity and infinity. The returned value is between −π and π. The result of ATAN2(*n,m*) is defined to be identical to ATAN(*n/m*).
BIN_TO_NUM(*b1, b2,…bn*)	Converts the bit vector represented by *b1* through *bn* into a number. Each of *b1* through *bn* must evaluate to either 0 or 1.
BITAND(*n*, *m*)	Performs a logical AND between *n* and *m*.
CEIL(*n*)	Returns the smallest integer greater than or equal to *n*.
COS(*n*)	Returns the cosine of the angle *n*, which must be expressed in radians.
COSH(*n*)	Returns the hyperbolic cosine of *n*. If *n* is a real number, and *i* is the imaginary square root of −1, then the relationship between COS and COSH can be expressed as follows: COS (*i* * *n*) = COSH (*n*).
EXP(*n*)	Returns the value *e* raised to the *n*th power, where *n* is the input argument. The number *e* (approximately equal to 2.71828) is the base of the system of natural logarithms.
FLOOR(*n*)	Returns the largest integer that is less than or equal to *n*.
GREATEST*(n1, n2,…n3)*	Returns the highest ordinal element from a list of input numbers.
LEAST*(n1, n2,…n3)*	Returns the lowest ordinal element from a list of input numbers.
LN(*n*)	Returns the natural logarithm of *n*. The argument *n* must be greater than or equal to 0.

Built-in function	Description
LOG(*b*, *n*)	Returns the base *b* logarithm of *n*. The argument *n* must be greater than or equal to 0. The base *b* must be greater than 1.
MOD(*n*, *m*)	Returns the remainder of *n* divided by *m*. The remainder is computed using a formula equivalent to *n*−(*m**FLOOR(*n*/*m*)) when *n* and *m* are both positive or both negative, and *n*−(*m**CEIL(*n*/*m*)) when the signs of *n* and *m* differ.
NANVL(*n*, *m*)	Returns *m* if *n* is NaN (not a number); otherwise, returns *n*. The value returned will be in the type of the argument with the highest numeric precedence: BINARY_DOUBLE, BINARY_FLOAT, or NUMBER, in that order.
POWER(*n*, *m*)	Raises *n* to the power *m*. If *n* is negative, then *m* must be an integer.
REMAINDER(*n*, *m*)	Returns the remainder of *n* divided by *m*. The remainder is defined as follows: *n* − (*m**ROUND(*n*/*m*)).
ROUND(*n*)	Returns *n* rounded to the nearest integer.
ROUND(*n*, *m*)	Returns *n* rounded to *m* decimal places. The value of *m* can be less than zero. A negative value for *m* directs ROUND to round digits to the left of the decimal point rather than to the right.
SIGN(*n*)	Returns −1, 0, or +1, depending on whether *n* is less than zero, equal to zero, or greater than zero.
SIN(*n*)	Returns the sine of the specified angle, which must be expressed in radians.
SINH(*n*)	Returns the hyperbolic sine of *n*. If *n* is a real number, and *i* is the imaginary square root of −1, then the relationship between SIN and SINH can be expressed as follows: SIN (*i* * *n*) = *i* * SINH (*n*).
SQRT(*n*)	Returns the square root *n*, which must be greater than or equal to 0.
TAN(*n*)	Returns the tangent of the angle *n*, which must be expressed in radians.

Built-in function	Description
TANH(*n*)	Returns the hyperbolic tangent of *n*. If *n* is a real number, and *i* is the imaginary square root of −1, then the relationship between TAN and TANH can be expressed as follows: TAN (*i* * *n*) = *i* * TANH (*n*).
TRUNC(*n* [, *p*])	Truncates *n* to *m* decimal places. The optional precision *p* defaults to 0 and, if negative, truncates (zeros out) *p* places to left of the decimal.

Datetime functions

Built-in function	Description
ADD_MONTHS(*date, n*)	Adds *n* months to *date*, returning a DATE.
CAST(*expression* AS *datatype*)	Converts *expression* to type *datatype*. You can use CAST to convert among datetime and string datatypes.
CURRENT_DATE	Returns the current date and time as a DATE value in the session time zone.
CURRENT_TIMESTAMP(*p*)	Returns the current date and time as a TIMESTAMP WITH TIME ZONE value in the session time zone. The optional precision *p* specifies the subsecond number of digits to the right of the decimal and defaults to 6.
DBTIMEZONE	Returns the time zone offset (from UTC) of the database time zone in the form of a character string.
EXTRACT(*element* FROM *expression*)	Returns the value of a specific datetime element from the datetime expression. The element can be one of YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, TIMEZONE_HOUR, TIMEZONE_MINUTE, TIMESONE_REGION, or TIMEZONE_ABBR.
FROM_TZ(*ts, tz*)	Adds time zone *tz* to TIMESTAMP *ts*, converting it to a TIMESTAMP WITH TIME ZONE.
LAST_DAY(*expression*)	Returns the last day in the month containing the DATE *expression*.

Built-in function	Description
LOCALTIMESTAMP(*p*)	Returns the current date and time as a TIMESTAMP value in the local time zone. The optional precision *p* specifies the subsecond number of digits to the right of the decimal.
MONTHS_BETWEEN(*end_date, start_date*)	Calculates the number of months between *start_date* and *end_date*.
NEW_TIME(*date,tz1,tz2*)	Translates the date value from time zone *tz1* to *tz2*. Included for backward compatibility; consider using a TIMESTAMP WITH TIMEZONE datatype instead.
NEXT_DAY(*date,dow*)	Returns the DATE of the first *dow* weekday that is later than *date*.
NUMTODSINTERVAL(*n, unit*)	Converts number *n* representing *unit* number to a value of type INTERVAL DAY TO SECOND. *unit* can be one of DAY, HOUR, MINUTE, or SECOND.
NUMTOYMINTERAL(*n, unit*)	Converts number *n* representing *unit* number to a value of type INTERVAL YEAR TO MONTH. *unit* can be one of YEAR or MONTH.
ROUND(*date, fmt*)	Returns *date* rounded to the optional format model *fmt* level of granularity. If *fmt* is not specified, *date* is rounded to the nearest day.
SESSIONTIMEZONE	Returns the time zone offset (from UTC) of the session time zone in the form of a character string.
SYSDATE	Returns the current date and time from the Oracle database server as a DATE value.
SYS_EXTRACT_UTC(*dt*)	Converts the TIMESTAMP WITH TIME ZONE value *dt* to a TIMESTAMP having the same date and time, but normalized to UTC.
SYSTIMESTAMP	Returns the current date and time from the Oracle database server as a TIMESTAMP WITH TIME ZONE value.
TO_CHAR(*dt, fmt*)	Converts the datetime *dt* to a string using optional format model *fmt*, which defaults to the session NLS_DATE_FORMAT.

Built-in function	Description
TO_DATE(*string, fmt*)	Converts *string* to a DATE; optionally use format model *fmt*, which defaults to the session NLS_DATE_FORMAT.
TO_DSINTERVAL(*string*)	Converts the character string representation of an interval expressed in days, hours, minutes, and seconds to a value of INTERVAL DAY TO SECOND.
TO_TIMESTAMP(*string, fmt*)	Converts the character string representation of a date and time to a value of type TIMESTAMP; optionally use format model *fmt,* which defaults to the session NLS_DATE_FORMAT.
TO_TIMESTAMP_TZ(*string, fmt*)	Converts the character string representation of a date and time to a value of type TIMESTAMP WITH TIME ZONE; optionally use format model *fmt*, which defaults to the session NLS_TIMESTAMP_FORMAT.
TO_YMINTERVAL(*string*)	Converts the character string representation of an interval expressed in years and months to a value of INTERVAL YEAR TO MONTH.
TRUNC(*date,fmt*)	Truncates the *date* value to format model *fmt* level of granularity. The default granularity is day.
TZ_OFFSET(*tz*)	Returns the time zone offset from UTC for *tz*, where *tz* is a time zone name, a time zone offset, or the keywords SESSIONTIMEZONE or DBTIMEZONE.

Built-in Regular Expression Functions

The Oracle database supports the use of regular expressions via five built-in functions: REGEXP_COUNT (new in Oracle Database 11*g*), REGEXP_INSTR, REGEXP_LIKE, REGEXP_REPLACE, and REGEXP_SUBSTR. For more details, see the *Oracle Regular Expressions Pocket Reference*, by Jonathan Gennick and Peter Linsley (O'Reilly).

Metacharacters

Regular expressions are found in Unix utilities such as *grep*, *sed*, and the *ex* editor, in the Perl scripting language, and in many other tools. Regular expressions are a powerful and popular means of processing text, mainly because they use *metacharacters* to facilitate searching for strings. The metacharacters supported by the database are shown in the following table:

Pattern metacharacter	Description
*	Asterisk. Matches zero or more occurrences.
+	Plus sign. Matches one or more occurrences.
?	Question mark. Matches zero or one occurrence.
^	Caret. Matches beginning of line.
$	Dollar sign. Matches end of line.
.	Period. Matches any single character.
\	Backslash. Treats the following metacharacter as a nonspecial character.
{*m*}	Curly braces. Matches exactly *m* times.
{*m*,}	Curly braces. Matches at least *m* times.
{*m*, *n*}	Curly braces. Matches at least *m* times, but no more than *n* times.
[]	Square brackets. Matches any of the characters in the square brackets.
|	Vertical bar. Alternation operator for specifying alternative matches.
( )	Parentheses. Grouping expression.
n	Backslash. Backreference expression (\1 through \9). Used in conjunction with ( ) to identify the *n*th occurrence of the backreferenced expression. (REGEXP_ REPLACE allows up to 500 backreferences in *replacement_string*.)
[: :]	Character class. Examples are [:digit:] for numeric digits or [:alnum:] for alphanumeric characters.

Pattern metacharacter	Description
[..]	Collation element. Encloses multiple characters treated as one character (e.g., 'ch' in Spanish).
[==]	Equivalence class. Matches accented and unaccented versions of a letter.

REGEXP_COUNT (Oracle Database 11g)

The REGEXP_COUNT function returns a number containing the tally of the occurences of a regular expression in a specific column, variable, or text literal. The syntax is:

```
REGEXP_COUNT (source_string, pattern [,postion
    [,match_modifier]])
```

where *source_string* is the character string to be searched, *pattern* is the regular expression pattern to search for in the *source_string*, and *match_modifier* is one or more modifiers that apply to the search (see the upcoming section, "Match modifiers"). For example:

```
phone_pattern := '\(?\d{3}\)?[\s.-]?\d{3}[\s.-]?\d{4}';
-- count the number of phone numbers in contact info
phone_count := regep_count(contact_clob,phone_pattern);
```

REGEXP_LIKE

The REGEXP_LIKE function determines whether a specific column, variable, or text literal contains text matching a regular expression. It returns Boolean TRUE if the regular expression is found in the *source_string* and FALSE if the regular expression is not found. The syntax is:

```
REGEXP_LIKE (source_string, pattern [,match_modifier])
```

where *source_string* is the character string to be searched, *pattern* is the regular expression pattern to search for in *source_string*, and *match_modifier* is one or more modifiers that apply to the search. For example:

```
IF REGEXP_LIKE(phone_number,'^\(?212\)?'
THEN
    -- phone number begins with 212
```

```
    -- optionally enclosed by parentheses
    APPLY_NYC_SURCHARGE;
END IF;
```

REGEXP_INSTR

The REGEXP_INSTR function locates, by character position, an occurrence of text matching a regular expression pattern. It returns the beginning or ending position of the regular expression within a string. The syntax is:

```
REGEXP_INSTR (source_string, pattern
[,beginning_position [,occurrence [,return_option
[,match_modifier [,subexp]]]]])
```

where *source_string* is a character string to be searched, *pattern* is a regular expression pattern to search for in *source_string*, *beginning_position* is the character position at which to begin the search, *occurrence* is the ordinal occurrence desired (1 = first, 2 = second, etc.), *return_option* is either 0 for the beginning position or 1 for the ending position, and *match_modifier* is one or more modifiers that apply to the search. For Oracle Database 11*g*, you can also specify *subexp*; if the pattern uses subexpressions, this parameter tells the database which subexpression to return the position of from the pattern found in the source string. Subexpressions are used to parse out the interesting pieces. You define a subexpression by enclosing it in parentheses. For example:

```
witty_saying := 'Man fears time, but time fears the
    Pyramids';
-- Display the witty_saying
-- starting with the second occurence of the word 'time'
DBMS_OUTPUT.PUT_LINE(SUBSTR(witty_saying
                    ,REGEXP_INSTR
                        (witty_saying,'time',1,2)));
```

The output is:

```
time fears the Pyramids
```

REGEXP_SUBSTR

The REGEXP_SUBSTR function extracts text matching a regular expression from a character column, variable, or text

literal. It returns as many matching substrings as it finds (which might be zero). The syntax is:

```
REGEXP_SUBSTR (source_string, pattern [,position
[,occurrence [,match_modifier [.subexp]]]])
```

where *source_string* is the character string to be searched, *pattern* is the regular expression pattern to search for in *source_string*, *position* is the character position at which to begin the search, *occurrence* is the ordinal occurrence desired (1 = first, 2 = second, etc.), and *match_modifier* is one or more modifiers that apply to the search. For Oracle Database 11*g*, you can also specify *subexp*; if the pattern uses subexpressions, this parameter tells the database which subexpression to return from the pattern found in the source string. For example:

```
-- get the leading number part of the address
-- (up to a whitespace character)
street_number := REGEXP_SUBSTR(address_line1,
    '[[:digit:]]+[:space:]');
```

In the following example, we parse out the exchange (second group of three digits) from the first telephone number found in the variable c_rec.c_clob. The regular expression pattern is defined as three digits optionally enclosed by parentheses; followed by an optional dot, dash, or whitespace character; followed by three digits; followed by an optional dot, dash, or whitespace character; followed by four digits. The whole pattern must match for the substring to be recognized as a matching pattern (telephone number). We then parse out the interesting part—the middle three digits—and assign it to the variable exchange. Here is the example data:

```
SELECT * FROM contacts WHERE contact_id=26;

CONTACT_ID CONTACT_NAME         CONTACT_CLOB
---------- -------------------- ------------------------
        26 Elwood Blues         Brother of "Joliet" Jake
                                address:
                                1060 W Addison St
                                Chicago, IL 60613
                                home 773-555-5253
                                club 312-555-2468
```

Next is the subexpression parsing example:

```
DECLARE
  ptrn      VARCHAR2(45);
  exchange  VARCHAR2(3);
  CURSOR c_cur IS
    SELECT contact_clob c_clob
    FROM contacts WHERE contact_id=26;
BEGIN
  ptrn:= '\(?(\d{3})\)?[\s.-]?(\d{3})[\s.-]?(\d{4})';
  -- Get the second subexpression from the first
  -- occurrence of the pattern
  FOR c_rec in c_cur LOOP
  exchange:=REGEXP_SUBSTR(c_rec.c_clob,ptrn,1,1,'i',2);
  DBMS_OUTPUT.PUT_LINE('exchange='||exchange);
  END LOOP;
END;
```

This displays:

```
exchange=555
```

REGEXP_REPLACE

The REGEXP_REPLACE function replaces a regular expression with new text that you specify. Your replacement text may include back references to values in the regular expression. The syntax is:

```
REGEXP_REPLACE (source_string, pattern
[,replacement_string [,position [,occurrence
[,match_modifier]]]])
```

where *source_string* is the character string to be searched, *pattern* is the regular expression pattern to search for in *source_string*, *replacement_string* is the replacement text for *pattern*, *position* is the character position at which to begin the search, *occurrence* is the ordinal occurrence desired (0 = all occurrences, 1 = first, 2 = second, etc.), and *match_modifier* is one or more modifiers that apply to the search. For example:

```
-- Change the domain part of the email addresses
-- Replace everything between the @ and the '.com' with
-- the new domain name
```

```
DBMS_OUTPUT.PUT_LINE(REGEXP_REPLACE(email_address
                     ,'@.*\.com','@new_domain.com'));
```

Match modifiers

The *match_modifiers* available to the regular expression condition and functions are shown in the following table:

match_modifier	Description
i	Uses a case-insensitive search; the default behavior is based on NLS_SORT.
c	Uses a case-sensitive search; the default behavior is based on NLS_SORT.
n	Enables the dot metacharacter to match newlines.
m	Treats the *source_string* as multiple lines for purposes of the beginning and end-of-line metacharacters ^ and $.

Built-in Packages

Oracle complements the basic built-in functions of PL/SQL with hundreds of supplied, or built-in, packages, all accessible from within PL/SQL programs. These packages (whose names start with "DBMS_" or "UTL_") provide you with a robust toolkit for meeting user requirements. The following table lists a small subset of the most commonly used packages and their programs. Check out the *Oracle Database PL/SQL Packages and Types Reference* (the official documentation of these packages from Oracle Corporation) for much more complete coverage of all of the officially supported built-in packages.

Built-in package/program	Description
DBMS_CRYPTO	Encrypts and decrypts data.
ENCRYPT	Encrypts RAW or LOB data using a stream or block cipher.
DECRYPT	Decrypts RAW or LOB data.
HASH	Creates a hash value (e.g., MD5, SHA-1) from RAW or LOB input.

Built-in package/program	Description
MAC	Creates a MAC code (e.g., MD5, SHA-1) from RAW or LOB input.
DBMS_DB_VERSION (no programs, only constants)	Provides absolute and relative information about the version of the database (Oracle Database 10*g* and above).
DBMS_ERRLOG	Allows an error-logging table to hold DML errors, letting you *continue past* DML errors (Oracle Database 10*g* Release 2 only).
CREATE_ERROR_LOG	Creates an error-logging table.
DBMS_LOCK	Provides an interface to lock management services.
SLEEP	Suspends execution for the given number of seconds (or less than a second).
DBMS_LOB	Provides an API to manage large objects (CLOBs, BLOBs, and BFILEs).
OPEN	Opens a LOB for manipulation.
CLOSE	Closes the LOB.
INSTR, SUBSTR, TRIM, APPEND	Performs data manipulation operations on the LOB.
CREATETEMPORARY, FREETEMPORARY, ISTEMPORARY	Works with temporary LOBs (reducing runtime overhead).
GETLENGTH	Gets the length of a LOB.
LOADFROMFILE, LOADBLOBLFROMFILE	Reads data from files into LOBs.
DBMS_METADATA	Reverse engineers database objects into the scripts that can be used to create them.
GET_XML	Returns metadata as an XML document.
GET_DDL	Returns a DDL statement as a CLOB.
SET_FILTER	Defines a filter restricting which objects are referenced from the data dictionary.
DBMS_OUTPUT	Displays information in system output (usually your monitor) from within a PL/SQL program.
ENABLE	Activates DBMS_OUTPUT, sending your text to the buffer.

Built-in package/program	Description
DISABLE	Turns off DBMS_OUTPUT so that your text is not sent to the buffer for display.
PUT_LINE	Writes a message followed by a newline character.
PUT	Writes a messages without a newline character.
NEW_LINE	Writes a newline character.
GET_LINE	Reads a line from the buffer up to the newline character.
GET_LINES	Reads an array of lines from the buffer.
DBMS_RLS	Implements row-level security (RLS) (aka virtual private database).
ADD_POLICY	Defines a new policy for a table.
DROP_POLICY	Drops a policy from a table.
EXECUTE	Executes a policy, allowing you to test its impact.
DBMS_SCHEDULER	Provides powerful, flexible job scheduling (available in Oracle Database 10*g* and above), replacing DBMS_JOB.
CREATE_JOB	Creates a job.
RUN_JOB	Runs a job.
DROP_JOB	Drops a job.
DBMS_SQL	Executes dynamic SQL statements, mostly used now for the more complex dynamic SQL requirements.
OPEN_CURSOR	Opens a cursor.
PARSE	Parses the dynamic SQL statement.
DEFINE_COLUMN	Defines an individual column, specifying its datatype.
BIND_VARIABLE	Binds a variable value to a placeholder.
EXECUTE	Executes the SQL statement.
EXECUTE_AND_FETCH	Executes the statement and fetches the first row.
FETCH_ROWS	Fetches one or more rows of data.

Built-in package/program	Description
COLUMN_VALUE	Extracts a column value from the fetched row.
CLOSE_CURSOR	Closes the cursor.
DBMS_UTILITY	Provides a wide variety of miscellaneous programs.
COMPILE_SCHEMA	Recompiles invalid program units.
EXEC_DDL_STATEMENT	Executes a DDL statement inside PL/SQL.
FORMAT_ERROR_STACK	Returns the nontruncated error message.
FORMAT_ERROR_BACKTRACE	Returns the trace of error propagation back to the line on which the error was originally raised.
FORMAT_CALL_STACK	Returns the execution call stack (that is, the stack of program calls that brought you to this point in your application code).
GET_TIME	Returns the current point in time down to the hundredth of a second; useful for calculating the elapsed time of programs.
GET_CPU_TIME	Returns the current point in time down to the hundredth of a second; useful for calculating the elapsed CPU time of programs.
HTF	Provides functions to generate HTML-compatible text, used for deploying PL/SQL-based Internet applications.
FORM* (e.g., FORMTEXT, FORMSUBMIT)	Manipulates the contents of an HTML form.
TABLE* (e.g., TABLEDATA, TABLECAPTION)	Manipulates the contents of an HTML table.
HTP	Provides procedures to generate HTML-compatible text, used for deploying PL/SQL-based Internet applications.
HTMLOPEN	Opens an HTML document.
HTMLCLOSE	Closes an HTML document.
PRINT	Sends text to the HTML buffer.
UTL_FILE	Reads from or writes to nondatabase text files.

Built-in package/program	Description
FOPEN	Opens a file for input or output.
ISOPEN	Determines whether a file is open.
FFLUSH	Flushes all buffered data to a file.
FCLOSE	Closes a file.
GET_LINE	Reads a line of text up to but not including the newline character.
PUT_LINE	Writes text to an open file followed by the newline character.
PUT	Writes text to an open file; does not include a newline character.
PUTF	Writes formated text to an open file.
NEW_LINE	Writes a newline character to an open file.
FGETPOS	Gets the current offset in bytes within an open file.
FSEEK	Adjusts the current offset within an open file.
FRENAME	Renames a file.
FREMOVE	Deletes a file.
UTL_MAIL	Sends email from a PL/SQL program to an SMTP server.
SEND	Sends an email message.
SEND_ATTACH_VARCHAR2	Sends an email with a text attachment.
SEND_ATTACH_RAW	Sends an email with a binary attachment.

Stored Procedures and Functions

PL/SQL allows you to create a variety of named program units, or containers, for your code. These include:

Procedure
  A program that executes one or more statements

Function
  A program that returns a value

Trigger
    A program that executes in response to database changes

Package
    A container for procedures, functions, and data structures

Object type
    Oracle's version of an object-oriented class; object types
    can contain member procedures and functions

The following sections describe stored procedures and functions. Later sections describe triggers, packages, and object types.

Procedures

Procedures are program units that execute one or more statements and can receive or return zero or more values through their parameter lists. The syntax of a procedure is:

```
CREATE [OR REPLACE] PROCEDURE name
   [ (parameter [,parameter]) ]
   [AUTHID { CURRENT_USER | DEFINER } ]
{ IS | AS }
   declaration_section
BEGIN
   executable_section
[EXCEPTION
   exception_section]
END [name];
```

Inside a PL/SQL executable section, a procedure is called as a standalone executable statement:

```
apply_discount(new_company_id, 0.15);
```

Many execution environments, such as SQL*Plus, also support ANSI SQL's CALL syntax:

```
CALL apply_discount(new_company_id, 0.15);
```

However, SQL*Plus programmers commonly invoke procedures with the SQL*Plus EXECUTE command:

```
EXECUTE apply_discount(new_company_id, 0.15);
```

or the equivalent anonymous block:

```
BEGIN
   apply_discount(new_company_id, 0.15);
END;
```

Functions

Functions are program units that execute zero or more statements and return a value through the RETURN clause. Functions also can receive or return zero or more values through their parameter lists. The syntax of a function is:

```
CREATE [OR REPLACE] FUNCTION name
   [ (parameter [,parameter]) ]
   RETURN return_datatype
   [AUTHID { CURRENT_USER | DEFINER } ]
   [DETERMINISTIC]
   [PARALLEL_ENABLE [partition_clause]]
   [PIPELINED [USING implementation_type]]
   [RESULT_CACHE [RELIES_ON (table_list)]]
   [AGGREGATE USING implementation_type]
{ IS | AS }
   [declaration_section]
BEGIN
   executable_section
[EXCEPTION
   exception_section]
END [name];
```

A function must have at least one RETURN statement in the execution section. The RETURN clause in the function header specifies the datatype of the returned value.

See "Compiling Stored PL/SQL Programs" for information on the keywords OR REPLACE, AUTHID, DETERMINISTIC, PARALLEL_ENABLE, PIPELINED, and AGGREGATE USING. See "Privileges and Stored PL/SQL" for AUTHID. See "Function Result Cache" for RESULT_CACHE.

A function can be called anywhere that an expression of the same type can be used. You can call a function:

• In an assignment statement:
```
sales07 := tot_sales(2007,'C');
```

- To set a default value:

    ```
    DECLARE
       sales07 NUMBER DEFAULT tot_sales(2007,'C');
    BEGIN
    ```

- In a Boolean expression:

    ```
    IF tot_sales(2007,'C') > 10000
    THEN ...
    ```

- In a SQL statement:

    ```
    SELECT first_name, surname
       FROM sellers
    WHERE tot_sales(2007,'C') > 1000;
    ```

- As an argument in another program unit's parameter list.

Here, for example, max_discount is a programmer-defined function, and SYSDATE is a built-in function:

```
apply_discount(company_id, max_discount(SYSDATE));
```

Parameters

Procedures, functions, and cursors may have a parameter list. This list contains one or more parameters that allow you to pass information back and forth between the subprogram and the calling program. Each parameter is defined by its name, datatype, mode, and optional default value. The syntax for a parameter is:

```
parameter_name [mode] [NOCOPY] datatype
   [ { := | DEFAULT } value]
```

Datatype

The datatype can be any PL/SQL or programmer-defined datatype, but cannot be constrained by a size (NUMBER is valid, NUMBER(10) is not valid). The actual size of the parameter is determined from the calling program

```
CREATE OR REPLACE PROCEDURE empid_to_name
(in_id          emp.emp_id%TYPE -- Compiles OK
,out_last_name  VARCHAR2        -- Compiles OK
,out_first_name VARCHAR2(10)    -- Won't compile
) IS
...
```

The lengths of out_last_name and out_first_name are determined by the calling program:

```
DECLARE
   surname      VARCHAR2(10);
   first_name   VARCHAR2(10);
BEGIN
   empid_to_name(10, surname, first_name);
END;
```

Mode

The *mode* of a parameter specifies whether the parameter can be read from or written to, as shown in the following table:

Mode	Description	Parameter usage
IN	Read-only	The value of the actual parameter can be referenced inside the program, but the parameter cannot be changed.
OUT or IN OUT	Read/write	The program can both reference (read) and modify (write) the parameter.

If the mode is not explicitly defined, it defaults to IN.

OUT parameters are not the same as IN OUT parameters. When running the called program, the runtime engine ignores (sets to NULL) any argument value you supply for an OUT parameter; it preserves the value provided for an IN OUT. If an exception is raised during execution of a procedure or function, assignments made to OUT or IN OUT parameters get rolled back unless the parameter includes the NOCOPY option.

NOCOPY is a request to the compiler to make the parameter a call by reference instead of a call by value. Normally, PL/SQL passes IN/OUT parameters by value—a copy of the parameter is created for the subprogram. When parameter items get large, as collections and objects do, the copy can eat memory and slow down processing. NOCOPY asks PL/SQL to pass the parameter by reference, using a pointer to the single copy of the parameter.

The main disadvantage of NOCOPY is that when an exception is raised during execution of a program that has modified an OUT or IN OUT parameter, the changes to the actual parameters are not "rolled back" because the parameters were passed by reference instead of being copied. Also, NOCOPY does not always apply; see *Oracle PL/SQL Programming* for a list of cases in which the compiler ignores the NOCOPY request.

Default values

IN parameters can be given default values. If an IN parameter has a default value, you do not need to supply an argument for that parameter when you call the program unit. It automatically uses the default value. For example:

```
CREATE OR REPLACE PROCEDURE hire_employee
   (emp_id      IN VARCHAR2
   ,hire_date   IN DATE := SYSDATE
        -- same as DEFAULT SYSDATE
   ,company_id  IN NUMBER DEFAULT 1    -- same as := 1
   )
IS
   ...
```

Here are some example calls to the preceding procedure:

```
-- Use two default values.
hire_employee(new_empno);
-- Use one default value.
hire_employee(new_empno,'12-Jan-2007');
-- Use nontrailing default value, named notation.
hire_employee(emp_id=>new_empno, comp_id=>12);
```

Parameter-passing notations

Formal parameters are the names that are declared in the header of a procedure or function. *Actual parameters* (*arguments*) are the values or expressions placed in the parameter list when a procedure or function is called. In the empid_to_name example shown earlier in the "Datatype" section, the formal parameters to the procedure are in_id, out_last_name, and out_first_name. The actual parameters used in the call to this procedure are 10, surname, and first_name.

PL/SQL lets you use either of two styles for passing arguments in parameter lists:

Positional notation
> The default. Each value in the list of arguments supplied in the program call is associated with the parameter in the corresponding position.

Named notation
> Explicitly associates the argument value with its parameter by name (not position). When you use named notation, you can supply the arguments in any order, and you can omit IN arguments that have default values.

The call to the empid_to_name procedure is shown here with both notations:

```
BEGIN
   -- Implicit positional notation.
   empid_to_name(10, surname, first_name);

   -- Explicit named notation.
   empid_to_name(in_id=>10
      ,out_last_name=>surname
      ,out_first_name=>first_name);
END;
```

You may combine positional and named notation, as long as positional arguments appear to the left of any named notation arguments; for example:

```
empid_to_name(10, surname, out_first_name => first_name);
```

When calling stored functions from SQL, all versions of the Oracle database support positional notation; Oracle Database 11*g* introduced support for named and mixed notation as well.

Local Programs

A local program is a procedure or function that is defined in the declaration section of a PL/SQL block. The declaration of a local program must appear at the end of the declaration

section, after the declarations of any types, records, cursors, variables, and exceptions. A program defined in a declaration section may be referenced only within that block's execution and exception sections. It is not defined outside that block.

The following program defines a local procedure and function:

```
PROCEDURE track_revenue
IS
   l_total NUMBER;

   PROCEDURE calc_total (year_in IN INTEGER) IS
   BEGIN
      calculations here ...
   END;

   FUNCTION below_minimum (comp_id IN INTEGER)
      RETURN BOOLEAN
   IS
   BEGIN
      ...
   END;
BEGIN
   ...main procedure logic here
END;
```

Local programs may be overloaded with the same restrictions as overloaded packaged programs.

Program Overloading

PL/SQL allows you to define two or more programs with the same name within any declaration section, including a package specification or body. This is called *overloading*. If two or more programs have the same name, they must be different in some other way so that the compiler can determine which program should be used.

Here is an example of overloaded programs in a built-in package specification:

```
PACKAGE DBMS_OUTPUT
IS
```

```
      PROCEDURE PUT_LINE (a VARCHAR2);
      PROCEDURE PUT_LINE (a NUMBER);
      PROCEDURE PUT_LINE (a DATE);
   END;
```

Each PUT_LINE procedure is identical, except for the datatype of the parameter. That is enough difference for the compiler.

To overload programs successfully, one or more of the following conditions must be true:

- Parameters must differ by datatype family (number, character, datetime, or Boolean).
- The program type must be different (you can overload a function and a procedure of the same name and identical parameter list).
- The numbers of parameters must be different.

In general, you *cannot* overload programs if:

- Only the datatypes of the functions' RETURN clauses are different.
- Parameter datatypes are within the same family (CHAR and VARCHAR2, NUMBER and INTEGER, etc.).
- Only the modes of the parameters are different.

Starting with Oracle Database 10*g*, you can overload programs whose parameters differ only in numeric datatypes, as long as they are in different datatype "families." The runtime environment will search first for a matching program with a PLS_INTEGER (or BINARY_INTEGER) parameter; then it will try to match NUMBER, BINARY_FLOAT, and finally BINARY_DOUBLE, in that order. If you want to force the use of the faster IEEE 754 datatypes, you may need to use the TO_BINARY_FLOAT or TO_BINARY_DOUBLE functions on the input argument, or for literals, append with f or d, as discussed in the earlier "Numeric Literals" section.

Forward Declarations

Programs must be declared before they can be used. PL/SQL supports *mutual recursion*, in which program A calls program B, whereupon program B calls program A. To implement this mutual recursion, you must use a *forward declaration* of the programs. This technique declares a program in advance of the program definition, thus making it available for other programs to use. The forward declaration is the program header up to the IS/AS keyword:

```
PROCEDURE perform_calc(year_in IN NUMBER)
IS
   /* Forward declaration for total_cost
      function. */
   FUNCTION total_cost (...) RETURN NUMBER;

   /* The net_profit function can now use
      total_cost. */
   FUNCTION net_profit(...) RETURN NUMBER
   IS
   BEGIN
      RETURN total_sales(...) - total_cost(...);
   END;

   /* The total_cost function calls net_profit. */
   FUNCTION total_cost (...) RETURN NUMBER
   IS
   BEGIN
      IF net_profit(...) < 0
      THEN
         RETURN 0;
         ELSE
         RETURN...;
      END IF;
   END;
BEGIN /* procedure perform_calc */
   ...
END perform_calc;
```

Table Functions

Table functions are functions that can be called within the FROM clause of a query, as if they were relational tables. To

act as a table function, a function must have a header that is SQL-compatible (no Boolean arguments, for example), and the function must return a nested table or VARRAY, whose type is declared at the schema level.

Pipelined table functions are special cases of table functions that allow you to "pipe" data out of the function back to the calling query while the function is still executing. Here is a very simple example of a pipelined table function:

```
CREATE OR REPLACE TYPE num_tab_typ AS TABLE OF NUMBER
/

CREATE OR REPLACE FUNCTION piped_func(factor IN NUMBER)
   RETURN num_tab_typ PIPELINED AS
BEGIN
   FOR counter IN 1..1000
   LOOP
     PIPE ROW (counter*factor);
   END LOOP;
END piped_func;
/

SELECT COLUMN_VALUE FROM TABLE (piped_func (2))
 WHERE rownum < 5
```

Function Result Cache

With the PL/SQL function result cache, new in Oracle Database 11*g*, you can tell the database to retain the results of your function in a cache, located in the System Global Area (SGA), and available to all sessions that invoke the function. The RESULT_CACHE feature is best suited for functions that are executed relatively often (think every few seconds or minutes) against data that changes relatively slowly (think hourly or daily). Use the RELIES_ON clause to ensure that the function results are flushed whenever there is DML on any table or view used by the function. Each instance in a RAC environment has its own result cache, which may differ in which items are cached, but common items in different instances will never disagree with each other.

Whenever a result-cached function is called with new parameters, both the parameters and the return value are saved in the cache. When the result-cached function is called with cached parameters, whether from your session or from a different one, the results are returned from the cache instead of being calculated anew. These cached entries can be monitored with the V$RESULT_CACHE % series of data dictionary views. Tune the size and usage of the result cache with the RESULT_CACHE_SIZE and RESULT_CACHE_MODE initialization parameters and the DBMS_RESULT_CACHE built-in package.

To enable result caching for your function, it must not be:

- In an anonymous block
- Defined with invoker's rights
- A pipelined table function
- Defined with any OUT or IN OUT parameters
- Defined with any IN parameters of type BLOB, CLOB, NCLOB, REF CURSOR, object, or record
- Defined with a RETURN type of BLOB, CLOB, NCLOB, REF CURSOR, object, or compound datatype (record or collection) containing any of these unsupported types

Oracle reccomends but does not require that result-cached functions not modify the database state or external state. For example, result-cached functions should not call DBMS_OUTPUT or UTL_FILE or send email because these external operations will not execute consistently between result cache hits and misses. Recursive fuctions are good candidates for result caching. The factorial function is an example:

```
CREATE OR REPLACE FUNCTION factorial(n NUMBER)
RETURN NUMBER RESULT_CACHE IS
BEGIN
  IF n <= 1 THEN
    RETURN 1;
  ELSE
    RETURN n*factorial(n-1);
  END IF;
END;
```

For packaged functions, use the keyword RESULT_CACHE in both the package specification and the package body, but put the RELIES_ON clause in the package body:

```
CREATE OR REPLACE PACKAGE bi_sales IS
  FUNCTION avg_sales(cust_id IN NUMBER)
    RETURN NUMBER RESULT_CACHE;
END bi_sales;

CREATE OR REPLACE PACKAGE BODY bi_sales IS
  FUNCTION avg_sales(cust_id IN NUMBER)
    RETURN NUMBER RESULT_CACHE
    -- Create dependency on two tables
    RELIES_ON (sales_fact,time_dim) IS
  BEGIN
    RETURN cust_id; -- simulation only
  END;
END bi_sales;
```

Privileges and Stored PL/SQL

Stored SQL supports two models for addressing privileges at runtime. The default is *definer rights*, which tells the database that the privileges of the owner or definer of the program should be used. With the definer rights model, the owner of the program must have the required privileges granted directly to him—he cannot inherit the privileges from a role.

With *invoker rights*, the user who executes the program does so using his own privileges. Anonymous PL/SQL blocks always execute with invoker rights. To create a program that uses the invoker rights model, include the keywords AUTHID CURRENT_USER in your program's declaration.

Triggers

Triggers are programs that execute in response to changes in table data or certain database events. A predefined set of events can be "hooked" with a trigger, enabling you to

integrate your own processing with that of the database. A triggering event *fires* or executes the trigger.

There are three types of triggering events:

DML events
    Fire when an INSERT, UPDATE, or DELETE statement executes

DDL events
    Fire when a CREATE, ALTER, or DROP statement executes

Database events
    Fire when one of the predefined database-level events occurs

Complete lists of these events are included in later sections.

Creating Triggers

The syntax for creating a trigger on a DML event is:

```
CREATE [OR REPLACE] TRIGGER trigger_name
{ BEFORE | AFTER | INSTEAD OF | FOR } trigger_event
  ON {table_or_view_reference |
     NESTED TABLE nested_table_column OF view}
     [REFERENCING [OLD AS old] [NEW AS new]
       [PARENT AS parent]]
[FOR EACH ROW ]
[FOLLOWS other_trigger] [DISABLE]
[COMPOUND TRIGGER]
[WHEN trigger_condition]
trigger_body;
```

The syntax for creating a trigger on a DDL or database event is:

```
CREATE [OR REPLACE] TRIGGER trigger_name
{ BEFORE | AFTER } trigger_event
  ON [ DATABASE | schema ]
 [FOLLOWS other_trigger][DISABLE]
[WHEN trigger_condition]
trigger_body;
```

Trigger events are listed in the following table:

Trigger event	Description
INSERT	Fires whenever a row is added to the *table_ or_view_ reference*.
UPDATE	Fires whenever an UPDATE changes the *table_or_view_ reference*. UPDATE triggers can additionally specify an OF clause to restrict firing to updates OF certain columns.
DELETE	Fires whenever a row is deleted from the *table_or_ view_reference*. Does not fire on a TRUNCATE of the table.
ALTER	Fires whenever an ALTER statement changes a database object. In this context, objects are things such as tables or packages (found in ALL_OBJECTS). Can apply to a single schema or the entire database.
ANALYZE	Fires whenever the database collects or deletes statistics or validates the structure of a database object.
ASSOCIATE STATISTICS	Fires whenever the database associates a statistic type with a database object.
AUDIT	Fires whenever the database records an audit operation.
COMMENT	Fires whenever a comment on a database object is modified.
CREATE	Fires whenever a database object is created. Does not fire on CREATE CONTROLFILE statements.
DB_ROLE_CHANGE	In a Data Guard configuration, fires whenever a role change from primary to standby or standby to primary occurs. Only AFTER DB_ROLE_CHANGE triggers on the DATABASE are allowed.
DDL	Fires whenever one of the following events occurs: ALTER, ANALYZE, ASSOCIATE STATISTICS, AUDIT, COMMENT, CREATE, DISASSOCIATE, DROP, GRANT, NOAUDIT, RENAME, REVOKE, or TRUNCATE.
DISASSOCIATE STATISTICS	Fires whenever the database disassociates a statistic type from a database object.
DROP	Fires whenever a DROP statement removes an object from the database. In this context, objects are things such as tables or packages (found in ALL_OBJECTS). Can apply to a single schema or the entire database.

Trigger event	Description
GRANT	Fires whenever a system, role, or object privilege is assigned.
NOAUDIT	Fires whenever the database processes a NOAUDIT statement to stop auditing database operations.
RENAME	Fires whenever a RENAME statement changes a database object name.
REVOKE	Fires whenever a system, role, or object privilege is rescinded.
TRUNCATE	Fires whenever a TRUNCATE statement is processed to purge a table or cluster.
SERVERERROR	Fires whenever a server error message is logged. Only AFTER triggers are allowed in this context.
LOGON	Fires whenever a session is created (a user connects to the database). Only AFTER triggers are allowed in this context.
LOGOFF	Fires whenever a session is terminated (a user disconnects from the database). Only BEFORE triggers are allowed in this context.
STARTUP	Fires when the database is opened. Only AFTER triggers are allowed in this context.
SHUTDOWN	Fires when the database is closed. Only BEFORE triggers are allowed in this context.
SUSPEND	Fires whenever a server error causes a transaction to be suspended.

Triggers can fire BEFORE or AFTER the triggering event. AFTER DML triggers are slightly more efficient than BEFORE triggers.

The REFERENCING clause is allowed only for the data events INSERT, UPDATE, and DELETE. It lets you give a nondefault name to the old and new pseudo-records. These pseudo-records give the program visibility to the pre- and postchange values in row-level triggers. These records are defined like %ROWTYPE records, except that columns of type LONG or LONG RAW cannot be referenced. They are prefixed with a colon in the trigger body and referenced with

dot notation. Unlike other records, these fields can only be assigned individually—aggregate assignment is not allowed. All old fields are NULL within INSERT triggers, and all new fields are NULL within DELETE triggers. Parent fields are valid only in triggers on nested tables and refer to the current row in the parent table.

FOR EACH ROW defines the trigger to be a row-level trigger. Row-level triggers fire once for each row affected. The default is a statement-level trigger, which fires only once for each triggering statement.

Prior to Oracle Database 11g, you could not specify a firing order for multiple triggers on the same event. Starting with Oracle Database 11g, however, you can use the FOLLOWS keyword to define this firing order.

If you specify the DISABLE keyword in Oracle Database 11g, the database creates the trigger in a disabled state. You can then issue ALTER TRIGGER ENABLE or ALTER TABLE ENABLE ALL TRIGGERS to enable the trigger. Creating a trigger in a disabled state allows you to verify that it will compile and helps you avoid "ORA-04098: trigger NAME is invalid and failed re-validation" errors.

The WHEN *trigger_condition* specifies the conditions that must be met for the trigger to fire. Stored functions and object methods are not allowed in the trigger condition.

The trigger body is a standard PL/SQL block. For example:

```
CREATE OR REPLACE TRIGGER add_tstamp
   BEFORE INSERT ON emp
   REFERENCING NEW as new_row
   FOR EACH ROW
   FOLLOWS audit_emp
   BEGIN
      -- Automatically timestamp the entry.
      SELECT CURRENT_TIMESTAMP
        INTO :new_row.entry_timestamp
        FROM dual;
END add_tstamp;
```

Triggers are enabled by default on creation and can be disabled (so that they do not fire) with an ALTER statement, issued with the following syntax:

```
ALTER TRIGGER trigger_name { ENABLE | DISABLE };

ALTER TABLE table_name { ENABLE | DISABLE } ALL TRIGGERS;
```

Trigger Predicates

When using a single trigger for multiple events, use the trigger predicates INSERTING, UPDATING, and DELETING in the trigger condition to identify the triggering event, as shown in this example:

```
CREATE OR REPLACE TRIGGER emp_log_t
   AFTER INSERT OR UPDATE OR DELETE ON emp
   FOR EACH ROW
DECLARE
   dmltype  CHAR(1);
BEGIN
   IF INSERTING THEN
      dmltype := 'I';
      INSERT INTO emp_log (emp_no, who, operation)
         VALUES (:new.empno, USER, dmltype);
   ELSIF UPDATING  THEN
      dmltype := 'U';
      INSERT INTO emp_log (emp_no, who, operation)
         VALUES (:new.empno, USER, dmltype);
   END IF;
END;
```

DML Events

The DML events include INSERT, UPDATE, and DELETE statements on a table. An INSTEAD OF trigger is associated with a view and fires in lieu of DML to that view. Triggers on these events can be statement-level triggers (table only) or row-level triggers, and can fire BEFORE or AFTER the triggering event. BEFORE triggers can modify the data in affected rows, but perform an additional logical read. AFTER triggers do not perform this additional logical read and therefore perform

slightly better, but are not able to change the *:new* values. AFTER triggers are thus better suited for data-validation functionality. Triggers cannot be created on SYS-owned objects. The order in which these triggers fire, if present, is as follows:

1. BEFORE statement-level trigger
2. For each row affected by the statement
3. BEFORE row-level trigger
4. The triggering statement
5. AFTER row-level trigger
6. AFTER statement-level trigger

Compound DML Triggers

Compound triggers, new in Oracle Database 11*g*, allow you to combine up to four DML triggering events into a single coordinated program. These compound triggers let you share common elements (subprograms and state data) among the different triggering events; for example, you can use bulk binds in your DML trigger and achieve significantly better performance when several rows are affected by a statement.

A compound trigger has as many as four sections: a BEFORE STATEMENT section, a BEFORE EACH ROW section, an AFTER EACH ROW section, and an AFTER STATEMENT section. The FOR and COMPOUND TRIGGER keywords tell the database that the trigger is a compound trigger. In the compound trigger's declaration section, you declare the structures that are to be shared by all sections. These structures include the collections needed for bulk binds, variables, local programs, etc. This trigger data is created when the trigger fires and is automatically destroyed (cleaned up) when the triggering statement completes.

Here is an example of using a compound trigger to record audit information on changes to the salary column in the employee table. The example shows how this is done with

the old FOR EACH ROW technique as well as the newer, more efficient bulk binds:

```
-- First row-by-row way
CREATE OR REPLACE TRIGGER old_trg
  AFTER UPDATE OF salary ON employees
  FOR EACH ROW
BEGIN
  INSERT INTO employee_audit
    VALUES(:new.employee_id ,:old.salary
          ,:new.salary ,SYSTIMESTAMP);
END old_trg;

-- This next trigger is created disabled
-- and must be enabled for use
-- Here is the bulk binds way
CREATE OR REPLACE TRIGGER new_trg
  FOR UPDATE OF salary ON employees DISABLE
  COMPOUND TRIGGER
    -- General declarations here
    TYPE emp_aud_t IS TABLE OF employee_audit%ROWTYPE
      INDEX BY BINARY_INTEGER;
    emps emp_aud_t;
    cntr  PLS_INTEGER := 0;
    batch_size CONSTANT PLS_INTEGER := 100;
    -- local procedure
    PROCEDURE bulk_flush IS
    BEGIN
      FORALL idx IN 1..emps.count
        INSERT INTO employee_audit VALUES emps(idx);
      emps.delete;
      cntr := 0;
    END ;
  -- Each of the four possible sections is
  -- defined like this:
  AFTER EACH ROW IS
  BEGIN
    cntr := cntr+1;
    emps(cntr).employee_id := :new.employee_id;
    emps(cntr).old_salary := :old.salary;
    emps(cntr).new_salary := :new.salary;
    emps(cntr).change_ts := systimestamp;
    IF cntr >= batch_size THEN
      bulk_flush;
    END IF;
  END AFTER EACH ROW;
```

```
   -- Do the final flush in the
   -- after statement section
   AFTER STATEMENT IS
   BEGIN
     bulk_flush;
   END AFTER STATEMENT;
END new_trg;
```

DDL Events

The DDL events are ALTER, ANALYZE, ASSOCIATE STA-
TISTICS, AUDIT, COMMENT, CREATE, DISASSOCIATE,
DROP, GRANT, NOAUDIT, RENAME, REVOKE, and
TRUNCATE. These triggers fire whenever the respective DDL
statement is executed. DDL triggers can apply to either a sin-
gle schema or the entire database.

Database Events

The database events are SERVERERROR, LOGON,
LOGOFF, STARTUP, SHUTDOWN, and SUSPEND. Only
BEFORE triggers are allowed for LOGOFF and SHUT-
DOWN events. Only AFTER triggers are allowed for
LOGON, STARTUP, and SERVERERROR events. A SHUT-
DOWN trigger will fire on a SHUTDOWN NORMAL and a
SHUTDOWN IMMEDIATE, but not on a SHUTDOWN
ABORT.

Packages

A package is a collection of PL/SQL objects that are grouped
together. There are several benefits to using packages,
including information hiding, object-oriented design, top-
down design, object persistence across transactions, and
improved performance.

Elements that can be placed in a package include proce-
dures, functions, constants, variables, cursors, exception
names, and TYPE statements (for associative arrays, records,
REF CURSORs, etc.).

Package Structure

A package can have two parts: the specification and the body. The *package specification* is required and lists all the objects that are publicly available (i.e., may be referenced from outside the package) for use in applications. It also provides all the information a developer needs to use objects in the package; essentially, it is the package's API.

The *package body* contains all the code needed to implement procedures, functions, and cursors listed in the specification, as well as any private objects (accessible only to other elements defined in that package) and an optional initialization section.

If a package specification does not contain any procedures or functions, and no private code is needed, that package does not need to have a package body.

The syntax for the package specification is:

```
CREATE [OR REPLACE] PACKAGE package_name
[ AUTHID { CURRENT_USER | DEFINER } ]
{ IS | AS }
   [definitions of public TYPEs
   ,declarations of public variables, types, and objects
   ,declarations of exceptions
   ,pragmas
   ,declarations of cursors, procedures, and functions
   ,headers of procedures and functions]
END [package_name];
```

The syntax for the package body is:

```
CREATE [OR REPLACE] PACKAGE BODY package_name
   { IS | AS }
   [definitions of private TYPEs
   ,declarations of private variables, types, and objects
   ,full definitions of cursors
   ,full definitions of procedures and functions]
[BEGIN
   executable_statements
[EXCEPTION
   exception_handlers]]
END [package_name];
```

Specify the optional OR REPLACE to rebuild an existing package, preserving any EXECUTE privileges previously granted to other accounts. The declarations in the specifications cannot be repeated in the body. Both the execution section and the exception section are optional in a package body. If the execution section is present, it is called the *initialization section* and executes only once—the first time any package element is referenced during a session.

You must compile the package specification before the body specification. When you grant EXECUTE authority on a package to another schema or to PUBLIC, you are giving access only to the specification; the body remains hidden.

Here's an example of a package:

```
CREATE OR REPLACE PACKAGE time_pkg IS
   FUNCTION GetTimestamp RETURN DATE;
   PRAGMA RESTRICT_REFERENCES (GetTimestamp, WNDS);

   PROCEDURE ResetTimestamp(new_time DATE
      DEFAULT  SYSDATE);
END time_pkg;

CREATE OR REPLACE PACKAGE BODY time_pkg IS
   StartTimeStamp DATE := SYSDATE;
   -- StartTimeStamp is package data.

   FUNCTION GetTimestamp RETURN DATE IS
   BEGIN
      RETURN StartTimeStamp;
   END GetTimestamp;

   PROCEDURE ResetTimestamp(new_time DATE DEFAULT SYSDATE)
   IS
   BEGIN
      StartTimeStamp := new_time;
   END ResetTimestamp;

END time_pkg;
```

Referencing Package Elements

The elements declared in the specification are referenced from the calling application via dot notation:

```
package_name.package_element
```

For example, the built-in package DBMS_OUTPUT has a procedure PUT_LINE, so a call to this package would look like this:

```
DBMS_OUTPUT.PUT_LINE('This is parameter data');
```

Package Data

Data structures declared within a package specification or body, but outside any procedure or function in the package, are *package data*. The default lifetime of package data is your entire session, spanning transaction boundaries and acting as globals for your programs.

Keep the following guidelines in mind as you work with package data:

- The state of your package variables is not affected by COMMITs and ROLLBACKs.
- A cursor declared in a package has global scope. It remains OPEN until you close it explicitly or until your session ends.
- A good practice is to *hide* your data structures in the package body and provide "get and set" programs to read and write that data. This technique can help protect your data.

SERIALLY_REUSABLE Pragma

If you need package data to exist only during a call to the packaged functions or procedures and not between calls of the current session, you can potentially save runtime memory by using the pragma SERIALLY_REUSABLE. After each call, PL/SQL closes the cursors and releases the memory used

in the package. This technique is applicable only to large user communities executing the same routine. Normally, the database server's memory requirements grow linearly with the number of users; with SERIALLY_REUSABLE, this growth can be less than linear because work areas for package states are kept in a pool in the database's SGA and are shared among all users. This pragma must appear in both the specification and the body, as shown here:

```
CREATE OR REPLACE PACKAGE my_pkg IS
   PRAGMA SERIALLY_REUSABLE;
   PROCEDURE foo;
END my_pkg;

CREATE OR REPLACE PACKAGE BODY my_pkg IS
   PRAGMA SERIALLY_REUSABLE;
   PROCEDURE foo IS
   ...
END my_pkg;
```

Package Initialization

The first time a user references a package element, the entire package is loaded into the SGA of the database instance to which the user is connected. That code is then shared by all sessions that have EXECUTE authority on the package.

Any package data is then instantiated into the session's User Global Area (UGA), a private area in either the SGA or the Process Global Area (PGA). If the package body contains an initialization section, that code will be executed. The initialization section is optional and appears at the end of the package body, beginning with a BEGIN statement and ending with the EXCEPTION section (if present) or the END of the package.

The following package initialization section runs a query to transfer the user's minimum balance into a global package variable. Programs can then reference the packaged variable (via the function) to retrieve the balance, rather than execute the query repeatedly.

```
CREATE OR REPLACE PACKAGE usrinfo
IS
   FUNCTION minbal RETURN VARCHAR2;
END usrinfo;

CREATE OR REPLACE PACKAGE BODY usrinfo
IS
   g_minbal NUMBER; -- Package data
   FUNCTION minbal RETURN VARCHAR2
   IS
   BEGIN
       RETURN g_minbal;
   END;
BEGIN  -- Initialization section
   SELECT minimum_balance
     INTO g_minbal
     FROM user_configuration
    WHERE username = USER;
EXCEPTION
   WHEN NO_DATA_FOUND
   THEN g_minbal := NULL;
END usrinfo;
```

Calling PL/SQL Functions in SQL

Stored functions can be called from SQL statements in a manner similar to built-in functions such as DECODE, NVL, or RTRIM. This is a powerful technique for incorporating business rules into SQL in a simple and elegant way, but there are several caveats and restrictions.

The most notable caveat is that stored functions executed from SQL are not by default guaranteed to follow the statement-level read consistency model of the database. Unless the SQL statement and any stored functions in that statement are in the same read-consistent transaction (even if they are read-only), each execution of the stored function may look at a different time-consistent set of data. To avoid this potential problem, you need to ensure read consistency programmatically by issuing the SET TRANSACTION READ ONLY or SET TRANSACTION ISOLATION LEVEL SERIALIZABLE statement before executing your SQL

statement containing the stored function. A COMMIT or ROLLBACK then needs to follow the SQL statement to end this read-consistent transaction.

Calling a Function

The syntax for calling a stored function from SQL is the same as that used to reference it from PL/SQL:

```
[schema_name.][pkg_name.]func_name[@db_link]
    [parm_list]
```

schema_name is optional and refers to the user/owner of the function or package. *pkg_name* is optional and refers to the package containing the called function. *func_name* is required and is the function name. *db_link* is optional and refers to the database link name to the remote database containing the function. *parm_list* is optional, as are the parameters passed to the function.

The following are example calls to the GetTimestamp function in the time_pkg example seen earlier in the "Package Structure" section:

```
-- Capture system events.
INSERT INTO v_sys_event (timestamp, event, qty_waits)
    SELECT time_pkg.GetTimestamp, event, total_waits
    FROM v$system_event

-- Capture system statistics.
INSERT INTO v_sys_stat (timestamp, stat#, value)
    SELECT time_pkg.GetTimestamp, statistic#, value
    FROM v$sysstat;
```

There are several requirements for calling stored functions in SQL:

- All parameters must be IN; no IN OUT or OUT parameters are allowed.
- The datatypes of the function's parameters and RETURN must be compatible with RDBMS datatypes. You cannot have arguments or RETURN types such as BOOLEAN, programmer-defined record, associative array, etc.

- When calling stored functions from SQL, all versions of Oracle support positional notation; Oracle Database 11*g* has introduced support for named and mixed notation as well.

- The function must be stored in the database, not in a local program, Forms PL/SQL library, or form.

Calling Packaged Functions in SQL

Prior to Oracle8*i* Database, it was necessary to assert the purity level of a packaged procedure or function when using it directly or indirectly in a SQL statement. Beginning with Oracle8*i* Database, the PL/SQL runtime engine determines a program's purity level automatically if no assertion exists. The RESTRICT_REFERENCES pragma is still supported for backward compatibility, but is usually unnecessary.

The RESTRICT_REFERENCES pragma asserts a purity level. The syntax for the RESTRICT_REFERENCES pragma is as follows:

```
PRAGMA RESTRICT_REFERENCES (program_name | DEFAULT,
   purity_level);
```

The keyword DEFAULT applies to all methods of an object type or all programs in a package.

From one to five purity levels, in any order, can be in a comma-delimited list. The *purity level* describes to what extent the program or method is free of *side effects*. Side effects are listed in the following table with the purity levels they address:

Purity level	Description	Restriction
WNDS	Write No Database State	Does not execute any INSERT, UPDATE, or DELETE statements.
RNDS	Read No Database State	Does not execute any SELECT statements.
WNPS	Write No Package State	Does not modify any package variables.

Purity level	Description	Restriction
RNPS	Read No Package State	Does not read any package variables.
TRUST	—	Does not enforce the restrictions declared, but allows the compiler to trust that they are true.

Column/Function Name Precedence

If your function has the same name as a table column in your SELECT statement, and the function has no parameter, the column takes precedence over the function. To force the Oracle database to resolve the name to your function, prepend the schema name to it:

```
CREATE TABLE emp(new_sal NUMBER ...);
CREATE FUNCTION new_sal RETURN NUMBER IS ...;

SELECT new_sal FROM emp;       -- Resolves to column.
SELECT scott.new_sal FROM emp; -- Resolves to function.
```

Object-Oriented Features

In the Oracle database, an *object type* combines attributes (data structures) and methods (functions and procedures) into a single programming construct. The object type construct allows programmers to define their own reusable datatypes for use in PL/SQL programs and table and column definitions. An object type must be created in a database before it can be used in a PL/SQL program.

An instance of an object type is an *object* in the same way that a variable is an instance of a scalar type. Objects are either *persistent* (stored in the database) or *transient* (stored only in PL/SQL variables). Objects can be stored in a database as a row in a table (a row object) or as a column in a table. A table of row objects can be created with syntax such as this:

```
CREATE TABLE table_name OF object_type;
```

When stored in such a table, the object (row) has a system-generated Object IDentifier (OID) that is unique throughout the database.

Object Types

An object type has two parts: a specification and a body. The specification is required and contains the attributes and method specifications. The syntax for creating the object type specification is:

```
CREATE [OR REPLACE] TYPE obj_type_name
[ AUTHID { CURRENT_USER | DEFINER } ]
{ { IS | AS } OBJECT | UNDER parent_type_name }
(
   attribute_name datatype,...,
   [ [ [NOT] OVERRIDING ] [ [NOT] FINAL ] [ [NOT]
   INSTANTIABLE ] method_spec,...,]
   [PRAGMA RESTRICT_REFERENCES(program_name, purities)]
)
[ [NOT] FINAL ]
[ [NOT] INSTANTIABLE ];
```

where *method_spec* is one of the following:

```
MEMBER { PROCEDURE | FUNCTION } program_spec
```

or:

```
STATIC { PROCEDURE | FUNCTION } program_spec
```

or:

```
{ ORDER | MAP } MEMBER FUNCTION comparison_function_spec
```

or:

```
[ FINAL ] [ INSTANTIABLE ] CONSTRUCTOR FUNCTION
  RETURNING SELF AS RESULT constructor_function_spec
```

Attribute specifications must appear before method specifications. Object attributes, like table columns, are defined with a name and a datatype. The name can be any legal identifier, and the datatype can be almost any datatype known to SQL other than LONG, LONG RAW, ROWID, and UROWID. Attributes can be declared using other programmer-defined

object types or collection types, but not of the special types ANYTYPE, ANYDATA, or ANYDATASET. Attributes cannot be of datatypes unique to PL/SQL, such as BOOLEAN.

Method headers appear in the object type specification in a comma-delimited list. Unlike in a package specification, commas (not semicolons) terminate the object type program specifications. To support object comparisons and sorting, the type optionally can include one comparison method—either ORDER or MAP. Member methods can be overloaded in object types following the same rules as function and procedure overloading in packages.

Method "specs" that appear earlier in the syntax actually can be call specs for Java classes in the database or for external procedures written in C.

The syntax for creating the object type body is:

```
CREATE [OR REPLACE] TYPE BODY obj_type_name
{ IS | AS }
(
    method_implementation; [ method_implementation ... ]
)
;
```

Where *method_implementation* is one of:

```
MEMBER { PROCEDURE | FUNCTION } function_body
```

or:

```
STATIC { PROCEDURE | FUNCTION } function_body
```

or:

```
{ ORDER | MAP } MEMBER FUNCTION comparison_function_body
```

or:

```
[ FINAL ] [ INSTANTIABLE ] CONSTRUCTOR FUNCTION
    RETURNING SELF AS RESULT constructor_function_body
```

Again, the program bodies can be call specs to Java or C programs.

Type Inheritance

You can define subtypes of object types following a single-inheritance model. The database does not have a master root-level object; instead, each type is "standalone" unless declared otherwise.

The UNDER keyword specifies that the type exists as a subtype in a hierarchy. When you are using UNDER, the parent type must be marked NOT FINAL. By default, types are FINAL, meaning that you cannot declare a subtype of that type.

A subtype contains all the attributes and methods of its parent (supertype), and may contain additional attributes and methods. Methods can override corresponding methods from the parent. Changes to the supertype—such as the addition of attributes or methods—are reflected in the subtypes automatically.

By default, object types are INSTANTIABLE—that is, an invoking program may create an object of that type. The phrase NOT INSTANTIABLE indicates that you don't want any objects of the type, in which case the database will not create a constructor for it. This variation generally makes sense only with types that will serve as parents of other types.

Methods

There are four kinds of methods: *member*, *static*, *constructor*, and *comparison*.

Member methods

A member method is a procedure or function designated with the keyword MEMBER. Calling programs may invoke such a method only on objects that have been instantiated.

Static methods

A static method has no access to a current (SELF) object. Such a method is declared using the keyword STATIC and can be invoked at any time using *type.method* syntax.

Constructor methods

Even if you don't declare any methods, every instantiable object has a default constructor method that allows a calling program to create new objects of that type. This built-in method:

- Has the same name as the object type
- Is a function that returns an object of that type
- Accepts attributes in named or positional notation
- Must be called with a value (or NULL) for every attribute—there is no DEFAULT clause for object attributes
- Cannot be modified

You can replace this default constructor with your own using the CONSTRUCTOR FUNCTION syntax. This method must have the same name as the object type, but there are no restrictions on its parameter list. The RETURN clause of the constructor's header must be RETURN SELF AS RESULT. The database supports overloading of programmer-defined constructors. All nonstatic methods have the implied parameter SELF, which refers to the current instance of the object. The default mode for the SELF parameter is IN for functions and IN OUT for procedures. A programmer can alter the mode by explicitly including SELF in the formal parameter list. An example of a programmer-defined default constructor follows:

```
CREATE OR REPLACE TYPE book_t AS OBJECT (
    isbn VARCHAR2(13),
    pages INTEGER,
```

```
CONSTRUCTOR FUNCTION book_t
    (id IN INTEGER DEFAULT NULL,
    title IN VARCHAR2 DEFAULT NULL,
    isbn IN VARCHAR2 DEFAULT NULL,
    pages IN INTEGER DEFAULT NULL)
    RETURN SELF AS RESULT,

OVERRIDING MEMBER FUNCTION ck_digit_okay
    RETURN BOOLEAN,

OVERRIDING MEMBER FUNCTION print
    RETURN VARCHAR2
);
```

Comparison methods

The comparison methods, ORDER and MAP, establish ordinal positions of objects for comparisons such as "<" or "between" and for sorting (ORDER BY, GROUP BY, DISTINCT). The database invokes a comparison method automatically whenever it needs to perform such an operation.

MAP and ORDER methods are actually special types of member methods—that is, they execute only in the context of an existing object. An ORDER function accepts two parameters: SELF and another object of the same type. It must return an INTEGER value as explained in the following table:

Return value	Object comparison
Any negative integer (commonly −1)	SELF < second object
0	SELF = second object
Any positive integer (commonly 1)	SELF > second object
NULL	Undefined comparison: attributes needed for the comparison are NULL

For example, the Senate ranks majority party members higher than nonmajority party members and within the majority (or nonmajority) by years of service. Here is an example ORDER function incorporating these rules:

```
CREATE TYPE senator_t AS OBJECT (
   majority boolean_t,
   yrs_service NUMBER,
   ORDER MEMBER FUNCTION ranking (other IN
      senator_t)
      RETURN INTEGER);

CREATE OR REPLACE TYPE BODY senator_t AS
   ORDER MEMBER FUNCTION ranking (other IN
      senator_t)
      RETURN INTEGER IS
   BEGIN
      IF SELF.majority.istrue( )
         AND other.majority.istrue( )
      THEN RETURN SIGN(SELF.yrs_service -
            other.yrs_service);
         ELSIF SELF.majority.istrue( )
            AND other.majority.isfalse( )
         THEN RETURN 1;
         ELSIF SELF.majority.isfalse( )
            AND other.majority.istrue( )
         THEN RETURN -1;
         ELSIF SELF.majority.isfalse( )
            AND other.majority.isfalse( )
         THEN RETURN SIGN(SELF.yrs_service -
            other.yrs_service);
         END IF;
   END ranking;
END;
```

A MAP function accepts no parameters and returns a scalar datatype such as DATE, NUMBER, or VARCHAR2 for which the database already knows a collating sequence. The MAP function translates, or *maps*, each object into this scalar datatype space.

If no ORDER or MAP function exists for an object type, then SQL, but not PL/SQL, supports only limited equality comparisons of objects. Objects are equal if they are of the same object type and if each attribute is equal.

Use MAP if possible when frequently sorting or comparing a large number of objects, as in a SQL statement; an internal optimization reduces the number of function calls. With ORDER, the function must run once for every comparison.

Methods in Subtypes

When defining methods in a subtype, you have two options: you can *inherit* a supertype's method, or you can *override* a supertype's method by defining your own subtype method of the same name and parameter list. If you choose to inherit, you do not need to write any code in the subtype.

To override a supertype, you must use the OVERRIDING keyword in the header of the program, as shown here:

```
CREATE TYPE food_t AS OBJECT (
    name VARCHAR2(100),
    food_group  VARCHAR2 (100),
    MEMBER FUNCTION price RETURN NUMBER
    )
    NOT FINAL
    ;

CREATE TYPE dessert_t UNDER food_t (
    contains_chocolate CHAR(1),
    OVERRIDING MEMBER FUNCTION price RETURN NUMBER
    )
    ;
```

This example also shows that if you want to allow a method to be overridden, you must specify that this method be NOT FINAL. By default, methods are FINAL and cannot be overridden.

You also can define a method to be NOT INSTANTIABLE, which means that you specify only the header of the method, but you do not need to provide an implementation in the OBJECT TYPE body for that method. For example:

```
CREATE TYPE food_t AS OBJECT (
    name VARCHAR2(100),
    food_group  VARCHAR2 (100),
    NOT INSTANTIABLE MEMBER FUNCTION price RETURN NUMBER
    )
    NOT FINAL
    NOT INSTANTIABLE
    ;
```

The consequences of a NOT INSTANTIABLE method are as follows:

- The entire object type must be defined as NOT INSTANTIABLE, which means that you cannot instantiate an instance from this type. You can use it only as a supertype in an object type hierarchy.
- Any subtype of food_t must provide an implementation of the price function or in turn also be defined as a NOT INSTANTIABLE object type.

The database supports *dynamic method dispatch*, also known as *dynamic polymorphism*, to determine which overridden method to invoke at runtime. That is, it will choose the method in the most specific subtype associated with the currently instantiated object. However, using the "generalized invocation" syntax introduced in Oracle Database 11*g*, it is possible to directly invoke a parent type's method. For example, you can invoke the food_t version of a dessert's price method using the following syntax:

```
DECLARE
   my_dessert dessert_t := dessert_t('tres leches',
      'sugar', 'N');
BEGIN
   DBMS_OUTPUT.PUT_LINE( (my_dessert AS food_t).price );
END;
```

This is also possible inside the implementation sections of subtype methods using SELF:

```
(SELF AS parent_type).method_invocation;
```

Manipulating Objects in PL/SQL and SQL

Variables declared as objects begin their life *atomically null*, meaning that the expression:

```
object IS NULL
```

evaluates to TRUE. Attempting to assign values to the attributes of an atomically null object will return an

ACCESS_ INTO_NULL exception. Instead, you must initialize the object, in one of these ways:

- Use either the default constructor method or a user-defined constructor.
- Assign to it the value of an existing object.
- Use SELECT INTO or FETCH INTO.

Here is an example using each initialization technique:

```
DECLARE
   project_boiler_plate  project_t;
   build_web_site        project_t;

   -- Initialize via constructor.
   new_web_mgr  proj_mgr_t :=
       proj_mgr_t('Ruth', 'Home Office');

   -- Initialize via user-defined constructor
   -- that provides defaults
   new_web_mgr proj_mgr_t := NEW proj_mgr_t();

   CURSOR template_cur IS
      SELECT VALUE(proj)
        FROM projects
       WHERE project_type = 'TEMPLATE'
         AND  sub_type = 'WEB SITE';
BEGIN
   OPEN template_cur;
   -- Initialize via FETCH INTO.
   FETCH template_cur
      INTO project_boiler_plate;

   -- Initialize via assignment.
   build_web_site := project_boiler_plate;
   ...
```

After an object is initialized, it can be stored in the database, and you can then locate and use that object with the REF, VALUE, and DEREF operators.

Upcasting and Downcasting

The Oracle database supports implicit *upcasting* (widening) of a subtype and provides the TREAT operator to *downcast* (narrow) a supertype. TREAT also can explicitly upcast a subtype.

The following example returns to the food-dessert hierarchy to demonstrate upcasting and downcasting:

```
CREATE TYPE food_t AS OBJECT (
   name VARCHAR2(100),
   food_group  VARCHAR2 (100)
   )
   NOT FINAL
   ;
/
CREATE TYPE dessert_t UNDER food_t (
   contains_chocolate CHAR(1)
   )
   ;

DECLARE
   marzipan dessert_t :=
      NEW dessert_t('marzipan', 'sweets', 'N');
   ice_cream_sundae dessert_t;
   tasty_treat food_t;
BEGIN
   /* An implied upcast */
   tasty_treat := marzipan;

   /* An explicit downcast */
   ice_cream_sundae := TREAT(tasty_treat AS dessert_t);
END;
```

The syntax of TREAT is:

```
TREAT (object_instance AS [REF] type)
```

where *object_instance* is a value that is of a particular supertype in an object hierarchy, and *type* is the name of the subtype (or supertype) in the same hierarchy. The TREAT expression won't compile if you attempt to cast a type to another from a different type hierarchy. If you supply an

object from the correct type hierarchy, TREAT will return either the casted object or NULL—but not an error.

You also can use dot notation to obtain access to the casted object's attributes and methods:

```
TREAT (object_instance AS type).{ attribute |
       method(args...) } ]
```

SQL also supports TREAT and implied upcasting.

REF operator

REF, short for REFerence, designates a datatype modifier or an operator to retrieve a logical pointer to an object. This pointer encapsulates the OID and can simplify navigation among related database objects. The syntax for a REF operator is:

```
REF(table_alias_name)
```

For example:

```
SELECT REF(p) FROM pets p WHERE ...
```

A PL/SQL variable can hold a reference to a particular object type:

```
DECLARE
   petref REF Pet_t;
BEGIN
   SELECT REF(p) INTO petref FROM pets p WHERE ...
```

Through deletions, REFs can reference a nonexistent object, called a *dangling REF*, resulting in a state that can be detected with the IS DANGLING predicate. For example:

```
UPDATE pets
   SET owner_ref = NULL
 WHERE owner_ref IS DANGLING;
```

The built-in package UTL_REF provides programmatic access to stored objects via their REF.

VALUE operator

Use the VALUE operator to retrieve a row object as a single object rather than as multiple columns. The syntax for the VALUE operator is:

```
VALUE(table_alias_name)
```

For example:

```
SELECT VALUE(p) FROM pets p WHERE ...
```

DEREF operator

Use the DEREF operator to retrieve the value of an object for which you have a REF. The syntax for DEREF is:

```
DEREF(table_alias_name)
```

For example:

```
DECLARE
   person_ref    REF person_t;
   author        person_t;
BEGIN
   -- Get the ref.
   SELECT REF(p) INTO person_ref
      FROM persons WHERE p.last_name ='Pribyl';

   -- Dereference the pointer back to the value.
   SELECT DEREF(person_ref) INTO author FROM dual;
```

In addition, the database uses an OID internally as a unique identifier for each object. As with a ROWID, you don't typically use an OID directly. The following table shows ways of referencing persistent objects:

Scheme	Description	Applications
OID	An opaque, globally unique handle, produced when the object is stored in the database as a table (row) object.	The persistent object's handle; it is what REFs point to. Your program never uses it directly.
VALUE	An operator. In SQL, it acts on an object in an object table and returns the object's *contents*. Different from the VALUES keyword found in some INSERT statements.	Used when fetching a table (row) object into a variable, or when you need to refer to an object table as an object instead of a list of columns.

Scheme	Description	Applications
REF	A pointer to an object. May be used within a SQL statement as an operator or in a declaration as a type modifier.	Allows quasi-normalizing of object-relational databases and joining of object tables using dot navigation. In PL/SQL, REFs serve as input/output variables.
DEREF	Reverse pointer lookup for REFs.	Used for retrieving the contents of an object when all you know is its REF.

Changing Object Types

You can add methods, but not attributes, to an object type stored in the database using the ALTER TYPE statement. There are several forms of this statement:

```
ALTER TYPE typename
    { ADD | MODIFY | DROP } ATTRIBUTE attribute_spec
    { INVALIDATE | CASCADE
    { [ NOT ] INCLUDING TABLE DATA |
        CONVERT TO SUBSTITUTABLE }
    [ FORCE ] };

ALTER TYPE typename
    [ NOT ] { INSTANTIABLE | FINAL }
    { INVALIDATE | CASCADE
        { [ NOT ] INCLUDING TABLE DATA |
            CONVERT TO SUBSTITUTABLE }
        [ FORCE ] };

ALTER TYPE typename
    COMPILE [ DEBUG ] [ SPECIFICATION | BODY ]
            [ REUSE SETTINGS ];
```

Because altering the structure of a type can have quite a few repercussions for database objects, the database requires that you either INVALIDATE the dependent objects or CASCADE the change.

When making a change from FINAL to NOT FINAL and cascading the change, you can cause existing table objects to be either NOT SUBSTITUTABLE (the default) or SUBSTITUTABLE. The following is an example of adding an attribute:

```
ALTER TYPE catalog_item_t
   ADD ATTRIBUTE publication_date VARCHAR2(400)
   CASCADE INCLUDING TABLE DATA;
```

The next example shows adding a method:

```
ALTER TYPE catalog_item_t
   ADD MEMBER PROCEDURE save,
   CASCADE;
```

After adding a method to a spec, you would use CREATE OR REPLACE TYPE BODY to implement it in the body (include all the other methods as well).

There are a variety of restrictions on modifying types; for example, you cannot change a type from INSTANTIABLE to NOT INSTANTIABLE if you have created tables that depend on the type.

The syntax for dropping an object type is:

```
DROP TYPE typename [FORCE];
```

You can drop only an object type that has not been implemented in a table (or you can drop the tables first). The FORCE option will drop object types even if they have dependencies, but FORCE will irreversibly invalidate any dependent objects such as tables. FORCE does not do a DROP CASCADE.

If you are dropping a type whose parent type has table dependents, this form of the statement:

```
DROP TYPE subtype_name VALIDATE;
```

will "validate" the safety of dropping the subtype before performing it. That is, the database will perform the drop only if there are no objects of the subtype in any substitutable columns of the parent type.

Compilation

PL/SQL compilation is an area that has seen several improvements in recent database versions. These capabilities include

conditional compilation, informational warnings, optimization, and compilation to native code.

Compiling Stored PL/SQL Programs

The following keywords are available when creating stored programs:

OR REPLACE

Used to rebuild an existing program unit, preserving privileges granted on it.

AUTHID

Defines whether the program will execute with the privileges of, and resolve names like, the object owner (DEFINER), or as the user executing the function (CURRENT_USER). The default AUTHID is DEFINER. See the section "Privileges and Stored PL/SQL" for additional information.

DETERMINISTIC

Required for function-based indexes. A function is DETERMINISTIC if it always returns the same value when called with the same parameters. Deterministic functions do not meaningfully reference package variables or the database. The built-in INITCAP is deterministic, but SYSDATE is not.

PARALLEL_ENABLED [(PARTITION in_parm BY {ANY | HASH | RANGE})]

Tells the optimizer that a function is safe for parallel execution. The PARTITION BY clause is available only to functions that have a REF CURSOR IN parameter. This clause is used with table functions and tells the optimizer how the input can be partitioned.

PIPELINED

Used with table functions. Specifies that the results of this table function should be returned iteratively via the PIPE ROW statement. A pipelined function can start to return data as it is generated instead of all at once after processing is complete.

AGGREGATE USING

> Required for aggregate functions. Tells the database that the function evaluates a group of rows and returns a single result. For example, the built-in function AVG is an aggregate function.

The following compiler settings are established at program creation time based on the database or session configuration and can be changed or retained during recompilation. The database stores these compiler settings on a program-by-program basis, so you can recompile your program later using the REUSE SETTINGS option. If you do not reuse the stored settings, or if you explicitly define one or more settings, your current session settings are used.

PLSQL_CCFLAGS

> Contains a comma-delimited list of name:value pairs controlling conditional compilation. See the upcoming "Conditional Compilation" section for more information.

PLSQL_CODE_TYPE

> Controls whether interpreted or native code is created during compilation. Valid values are INTERPRETED or NATIVE. See the "Performing Native Compilation of PL/SQL" section for more information.

PLSQL_DEBUG

> Controls whether or not the program will be instrumented for debugging during compilation. Valid values are TRUE or FALSE. When compiled for debugging, a program will always be INTERPRETED and never NATIVE.

PLSQL_OPTIMIZE_LEVEL

> Controls the level of optimization employed by the compiler. Valid values are 0, 1, 2, or 3. See the "Optimizing Compiler" section for more information.

PLSQL_WARNINGS

> Controls the level of warnings that the compiler will report. See the "Compiler Warnings" section for more information.

NLS_LENGTH_SEMANTICS
> Controls whether VARCHAR2 and CHAR datatypes are defined with BYTE (default) or CHAR semantics. NVARCHAR2, NCHAR, CLOB, and NCLOB datatypes are always defined with CHAR semantics.

To recompile the procedure my_proc, explicitly setting the optimization level to 3, run the following:

```
ALTER PROCEDURE my_proc COMPILE PLSQL_OPTIMIZE_ LEVEL = 3;
```

Then to recompile it later with the saved settings, run the following:

```
ALTER PROCEDURE my_proc COMPILE REUSE SETTINGS;
```

To view all of the stored compiler settings for your programs, query the view USER_PLSQL_OBJECT_SETTINGS.

Conditional Compilation

Conditional compilation, introduced with Oracle Database 10*g* (patch level 10.1.0.4), allows your programs to decide at compile time which blocks of code will be implemented. You can conditionally include code in the compiled program based on the database version, environment, or other configurable settings. There are three types of compiler directives available for you to use:

Selection directives
> Use the $IF directive to evaluate an expression and determine which code should be included. For example:

```
CREATE OR REPLACE PROCEDURE new_emp IS
BEGIN
$IF DBMS_DB_VERSION.VER_LE_1O_2 $THEN
  -- Legacy code
  SELECT employees_seq.NEXTVAL
   INTO emp_rec.empno FROM dual;
$ELSIF DBMS_DB_VERSION.VER_LE_11 $THEN
  -- Oracle Database 11g code
  emp_rec.empno := employees_seq.NEXTVAL;
$ELSE
  -- Later releases than Oracle Database 11g
```

```
    emp_rec.empno := employees_seq.NEXTVAL;
$END
    INSERT INTO emp VALUES (emp_rec);
END;
```

Inquiry directives

Use the $$identifier directive to refer to conditional compilation flags (PLSQL_CCFLAGS). These inquiry directives can be referenced in an $IF directive or independently. For example:

```
ALTER SESSION SET PLSQL_CCFLAGS =
  'pl_debug:false, pl_trace_level:2';

CREATE OR REPLACE PROCEDURE extract_client_data
IS
BEGIN
$IF $$pl_debug OR $$pl_trace_level >= 2 $THEN
  DBMS_SUPPORT.START_TRACE(waits=>TRUE, binds=>TRUE);
$ELSIF $$pl_trace_level >= 1 $THEN
  DBMS_SUPPORT.START_TRACE(waits=>TRUE, binds=>FALSE);
$END
  NULL; -- code goes here
END extract_client_data;
```

Error directives

Use the $ERROR directive to force compilation errors if your prerequisite conditions are not met. For example:

```
CREATE OR REPLACE PROCEDURE long_compilation IS
BEGIN
$IF $$plsql_optimize_level <> 1
$THEN
   $error 'Program must be compiled with optimization
level = 1' $end
$END
   NULL;
END long_compilation;
```

The settings that are available for use in these directives include:

Compiler settings

PLSQL_CCFLAGS, PLSQL_DEBUG, PLSQL_WARNINGS, PLSQL_OPTIMIZE_LEVEL, PLSQL_CODE_TYPE, and NLS_LENGTH_SEMANTICS.

PLSQL_LINE (PLS_INTEGER literal)
   The line number within the program or can be explicitly defined with the PLSQL_CCFLAGS parameter.

PLSQL_UNIT (VARCHAR2 literal)
   The name of the program being compiled. For anonymous blocks, it is null. PLSQL_UNIT can also be explicitly defined with the PLSQL_CCFLAGS parameter.

Static expressions defined in package specifications
   These expressions cannot change when a package is recompiled.

The PL/SQL compiler reads and interprets these directives, generating the code to be implemented. To identify what has actually been deployed in the compiled program, use the DBMS_PREPROCESSOR package, as in the following example:

```
-- Create a conditionally compiled program
CREATE OR REPLACE PROCEDURE my_cc_proc IS
BEGIN
  DBMS_OUTPUT.PUT_LINE('DB Version is:'
     ||DBMS_DB_VERSION.VERSION||'r'
     ||DBMS_DB_VERSION.RELEASE);
$IF DBMS_DB_VERSION.VER_LE_10_2 $THEN
  DBMS_OUTPUT.PUT_LINE('Version 10r2 code here');
$ELSIF DBMS_DB_VERSION.VER_LE_11 $THEN
  DBMS_OUTPUT.PUT_LINE('Version 11 code here');
$ELSE
  DBMS_OUTPUT.PUT_LINE('Later than 11 code here');
$END
END;

-- Display the deployed code
BEGIN
DBMS_PREPROCESSOR.PRINT_POST_PROCESSED_SOURCE
  ('PROCEDURE', USER, 'MY_CC_PROC');
END;
```

This displays the deployed code:

```
PROCEDURE my_cc_proc IS
BEGIN
```

```
   DBMS_OUTPUT.PUT_LINE('DB Version is:'
       ||DBMS_DB_VERSION.VERSION
     ||'r'|| DBMS_DB_VERSION.VERSION);
   DBMS_OUTPUT.PUT_LINE('Version 10r2 code here');
END;
```

Compiler Warnings

Compile-time warnings can help make your programs more robust. These warnings highlight potential problems that are not severe enough to raise an exception, but may result in runtime errors or poor performance. You can configure the compiler to reject as an error any of these warnings. Warnings result in the program compiling to a VALID status, but errors result in an INVALID status.

To enable these warnings, you need to set the database initialization parameter PLSQL_WARNINGS. This parameter can be set globally in the *SPFILE* initialization file, in your session via the ALTER SESSION statement, or with the built-in package DBMS_WARNING.

The PLSQL_WARNINGS parameter is a comma-delimited list of values, each of which has the syntax:

```
[ENABLE | DISABLE | ERROR] : [ALL | SEVERE | INFORMATIONAL
| PERFORMANCE | warning_number]
```

For example, to enable all warnings in your session, execute:

```
ALTER SESSION SET plsql_warnings = 'enable:all'
```

If you want to configure Oracle Database 11*g* warning message number 06009 ("OTHERS handler does not end in RAISE or RAISE_APPLICATION_ERROR") as an error and enable all warnings in the performance category except warning number 07202 ("Parameter may benefit from use of the NOCOPY compiler hint"), execute:

```
ALTER SESSION SET plsql_warnings = 'error:06009'
                                  ,'enable:performance'
                                  ,'disable:07203';
```

To see what your current setting is, you can execute:

```
DBMS_OUTPUT.PUT_LINE (
    DBMS_WARNING.get_warning_setting_string());
```

Some examples of warnings follow:

```
SQL>ALTER SESSION SET plsql_warnings ='ENABLE:ALL',
    'ERROR:6009';
Session altered.

SQL>CREATE OR REPLACE PROCEDURE bad_practice IS
  2    test_string VARCHAR2(32);
  3  BEGIN
  4    test_string := 'My demo program';
  5  EXCEPTION

Optimizing Compiler

PL/SQL's optimizing compiler can improve runtime perfor-
mance dramatically while imposing only a relatively slight
overhead at compile time. Fortunately, the benefits of opti-
mization apply to both interpreted and natively compiled
PL/SQL because optimizations are applied by analyzing
patterns in source code.

The optimizing compiler is enabled by default. However, you may want to alter its behavior, by either lowering its aggressiveness or disabling it entirely. For example, if, in the course of normal operations, your system must perform recompilation of many lines of code, or if an application generates many lines of dynamically executed PL/SQL, the overhead of optimization may be unacceptable. Note, however, that Oracle's tests show that the optimizer doubles the runtime performance of computationally intensive PL/SQL.

In some cases, the optimizer may even alter program behavior. One such case might occur in code written for Oracle9*i* Database, which depends on the relative timing of initialization sections in multiple packages. If your testing demonstrates such a problem, yet you want to enjoy the performance benefits of the optimizer, you may want to rewrite the offending code or introduce an initialization routine that ensures the desired order of execution.

New to Oracle Database 11*g* is program *intra-unit inline optimization*. This optimization technique replaces a call to a subprogram with a copy of the program, at compile time. The performance improvement occurs because the subprogram does not have to be loaded separately at runtime. This technique is especially useful for short utility helper programs.

To change the optimizer settings, set the initialization parameter PLSQL_OPTIMIZE_LEVEL, either for your session with an ALTER SESSION statement or for the database with an ALTER SYSTEM statement. Valid settings are:

0   No optimization

1   Moderate optimization, such as eliminating superfluous code or exceptions

2 (default)
   Aggressive optimization beyond level 1, including rearranging source code

3 (Oracle Database 11g)
   Include inline subprogram optimization

You can also modify these settings for the current session; for example:

```
ALTER SESSION SET PLSQL_OPTIMIZE_LEVEL = 0;
```

With optimization level 2, you can control inline optimization with the INLINE pragma (see the earlier "Pragmas" section). The syntax of the INLINE pragma is:

```
PRAGMA INLINE (program_name,'YES | NO');
```

YES requests the compiler to use inline optimization for calls to *program_name*, while NO explicitly requests the compiler to not use inline optimization for such calls. In the following example, compiled with the default optimization level 2, calls to the procedure P are requested to be inlined:

```
CREATE OR REPLACE PACKAGE BODY bi_util IS
  FUNCTION avg_sales(cust_id IN NUMBER)
    RETURN NUMBER
  IS
  BEGIN
    PRAGMA INLINE (P,'YES'); -- inline calls to program P
    p('Inside simulation');
    RETURN cust_id; -- simulation only
  END;
END bi_util;
```

Performing Native Compilation of PL/SQL

Starting with Oracle9*i* Database, you can speed up many of your PL/SQL programs by compiling the stored programs natively. The database will translate your PL/SQL program into C code and compile it into a shared library (DLL on Microsoft Windows platforms). Prior to Oracle Database 11*g*, you had to have a supported C compiler on your database server machine to use native compilation. Using native compilation, you will realize the greatest performance gains with computer-intensive applications and the least from programs that contain only declarations, such as types and package specifications. Programs compiled for debug will never be compiled natively.

When a natively compiled program is first executed on some platforms and database releases, it is copied from a shared library in the system tablespace to the PLSQL_NATIVE_LIBRARY_DIR, where it is cached. On other platforms and database releases, this copy is not necessary.

Oracle9i Database

With Oracle9*i* Database, follow these steps to compile natively:

1. Edit the makefile, *spnc_makefile.mk*, which you should find in the *$ORACLE_HOME/plsql* subdirectory.

2. Set the initialization parameter PLSQL_COMPILER_FLAGS to 'NATIVE'. Individual developers may alter the value of PLSQL_COMPILER_FLAGS using the ALTER SESSION statement.

3. The following parameters may also need to be set: PLSQL_NATIVE_C_COMPILER, PLSQL_NATIVE_LINKER, PLSQL_NATIVE_LIBRARY_DIR, PLSQL_NATIVE_MAKE_UTILITY, and PLSQL_NATIVE_MAKE_FILE_NAME. The DBA can set these parameters in the database initialization file or use an ALTER SYSTEM statement.

4. If your system has more than 15,000 PL/SQL objects, it may take a long time to scan these in a single directory, so set PLSQL_NATIVE_DIR_SUBDIR_COUNT as shown previously and create the directories named *d0, d1, d2*, etc.

5. Create or replace your stored programs.

6. Verify the native compilation by querying the data dictionary view USER_STORED_SETTINGS and also by locating the shared library or DLL in the database server's filesystem.

Oracle Database 10g

With Oracle Database 10*g*, native compilation became much simpler to configure, in part because Oracle started using

database tables rather than files for permanent storage of the generated shared libraries. Oracle also limits support to the C compiler supplied by the platform vendor. Follow these steps to compile natively:

1. Inspect the file *$ORACLE_HOME/plsql/spnc_commands* and, if necessary, revise the path to the supported C compiler.

2. Set the parameter PLSQL_NATIVE_LIBRARY_DIR as shown previously and create this directory if it does not exist. This is the location in the filesystem that the database will use for an on-demand cache of the shared library files. The OFA standard locates this directory under one of the data file directories. For security reasons, only the ORACLE user should have write privileges on this and any PLSQL_NATIVE_DIR_SUBDIR directories.

3. If your system has more than 15,000 PL/SQL objects, it may take a long time to scan these in a single directory, so set PLSQL_NATIVE_DIR_SUBDIR_COUNT as shown previously and create the directories named *d0, d1, d2*, etc.

4. Either make a global change so that the database parameter PLSQL_CODE_TYPE is set to NATIVE, or issue a session-level statement:

   ```
   ALTER SESSION SET PLSQL_CODE_TYPE = 'NATIVE';
   ```

5. Create or replace your stored programs.

Oracle Database 11g

With Oracle Database 11*g*, a separate C compiler is no longer needed, nor is the *spnc_commands* file. The database compiles directly to shared libraries. Follow these steps:

1. On some platforms, you need to set the parameter PLSQL_NATIVE_LIBRARY_DIR as shown previously. Linux and Windows do not use this directory.

2. Either make a global change so that the database parameter PLSQL_CODE_TYPE is set to NATIVE, or issue a session-level statement:

```
ALTER SESSION SET PLSQL_CODE_TYPE = 'NATIVE';
```

3. Recompile your stored programs.

Java Language Integration

Java programmers can write server-side classes that invoke SQL and PL/SQL using standard JDBC or SQLJ calls. PL/SQL programmers can call server-side Java methods by writing a PL/SQL cover or *call spec* for Java using Oracle database DDL.

Server-side Java in the database may be faster than PL/SQL for computer-intensive programs, but not as nimble for database access. PL/SQL is much more efficient for database-intensive routines because, unlike Java, it doesn't have to pay the overhead for converting SQL datatypes for use inside the stored program. Database programmers will want to continue to use PL/SQL for programs that perform a lot of database I/O and use Java for the best raw computation performance. Follow these steps to create a Java stored procedure (JSP):

1. Write or otherwise obtain functional Java code. Having source code is not necessary, though, so you can use class libraries from third parties. The classes must, however, meet two requirements. Methods published to SQL and PL/SQL must be declared static; PL/SQL has no mechanism for instantiating nonstatic Java classes. In addition, the classes must not issue any GUI calls (for example, to AWT) at runtime.

   If you write your own JSP and it needs to connect to the database for access to tables or stored procedures, use standard JDBC and/or SQLJ calls in your code. Many JDBC and SQLJ reference materials are available to provide assistance in calling SQL or PL/SQL from Java, but be sure to review the product-specific documentation that ships with your tool.

---

2. Once you have the Java class in hand, either in source or *.class* file format, load it into the database. The database's *loadjava* command-line utility is a convenient way to accomplish the load. Refer to the *Oracle Java Developer's Guide* for further assistance with *loadjava*.

3. Create a call spec for the Java method, specifying the AS LANGUAGE JAVA clause of the CREATE statement (described in the "Publishing Java to PL/SQL" section). You may create a function or procedure cover as appropriate.

4. Grant EXECUTE privileges on the new JSP using GRANT EXECUTE; PL/SQL routines can now call the JSP as if it were another PL/SQL module.

Example

Let's write a simple "Hello, World" JSP that will accept an argument:

```
package oreilly.plsquick.demos;

public class Hello {
    public static String sayIt (String toWhom) {
        return "Hello, " + toWhom + "!";
    }
}
```

Saved in a file called *Hello.java*, the source code can be loaded directly into the database. Doing so will compile the code automatically. Here is a simple form of the *loadjava* command:

```
loadjava -user scott/tiger -oci8 oreilly/plsquick/
    demos/Hello.java
```

The *Hello.java* file follows the Java file placement convention for packages, and thus exists in a subdirectory named *oreilly/plsquick/demos*.

We can fire up our favorite SQL interpreter, connect as SCOTT/TIGER, and create the call spec for the `Hello.sayIt()` method:

```
CREATE FUNCTION hello_there (to_whom IN VARCHAR2)
   RETURN VARCHAR2
   AS LANGUAGE JAVA
   NAME 'oreilly.plsquick.demos.Hello.sayIt
     (java.lang.String) return java.lang.String';
```

Now we can call our function very easily:

```
BEGIN
   DBMS_OUTPUT.PUT_LINE(hello_there('world'));
END;
```

And we get the following as the expected output:

```
Hello, world!
```

Publishing Java to PL/SQL

To write a call spec, use the AS LANGUAGE JAVA clause in a CREATE statement. The syntax for this clause is:

```
{ IS | AS } LANGUAGE JAVA
   NAME 'method_fullname [ (type_fullname,... ]
     [ RETURN type_fullname ]'
```

method_fullname is the package-qualified name of the Java class and method. It is case-sensitive and uses dots to separate parts of the package's full name. *type_fullname* is the package-qualified name of the Java datatype. Notice that a simple string, not a SQL name, follows the NAME keyword.

Type mapping follows most JDBC rules regarding the legal mapping of SQL types to Java types. JDBC extensions exist for Oracle-specific datatypes. Most datatype mappings are relatively straightforward, but passing database objects of a user-defined type is harder than one would think. Oracle provides a JPublisher tool that generates the Java required to encapsulate a database object and its corresponding REF. Refer to Oracle's JPublisher documentation for guidelines on usage.

The AS LANGUAGE JAVA clause is the same regardless of whether you are using Java as a standalone JSP, the implementation of a packaged program, or the body of an object type method. For example, here is the complete syntax for creating JSPs as PL/SQL-callable functions or procedures:

```
CREATE [OR REPLACE]
{ PROCEDURE procedure_name [(param[, param]...)]
  | FUNCTION function_name [(param[, param]...)]
      RETURN sql_type
}
[AUTHID {DEFINER | CURRENT_USER}]
[PARALLEL_ENABLE]
[DETERMINISTIC]
{ IS | AS } LANGUAGE JAVA
   NAME 'method_fullname [ (type_fullname,... ]
      [ RETURN type_fullname ]'
```

When using Java as the implementation of a packaged procedure or function, the database allows you to place the Java call spec either in the package specification (where the call spec substitutes for the subprogram specification) or in the package body (where the call spec substitutes for the subprogram body). Similarly, when using JSPs in object type methods, the Java call spec can substitute for either the object type method specification or its body.

Note that Java functions typically map to PL/SQL functions, but Java functions declared void map to PL/SQL procedures. Also, you will quickly learn that mistakes in mapping PL/SQL parameters to Java parameters become evident only at runtime.

Data Dictionary

To learn what Java library units are available in your schema, look in the USER_OBJECTS data dictionary view where the *object_type* is like "JAVA%". If you see a Java class with INVALID status, it has not yet been resolved successfully. Note that the names of the Java source library units need not match the names of the classes they produce.

O'REILLY®

Oracle PL/SQL Language Pocket Reference

The fourth edition of this popular pocket guide provides quick-reference information that will help you use Oracle's PL/SQL language, including the newest Oracle Database 11*g* features. It's a companion to Steven Feuerstein and Bill Pribyl's bestselling *Oracle PL/SQL Programming*.

This concise guide boils down the most vital PL/SQL information into an accessible summary of:

- Fundamental language elements (e.g., block structure, identifiers, datatypes, and declarations)
- Statements for program control, cursor management, exception handling, and calling PL/SQL functions in SQL
- Records, procedures, functions, triggers, and packages
- Compilation options, object-oriented features, and collections

This new edition describes such Oracle Database 11*g* elements as PL/SQL's function result cache, compound triggers, the CONTINUE statement, the SIMPLE_INTEGER datatype, and improvements to native compilation, regular expressions, and compiler optimization (including intra-unit inlining). In addition, this book now includes substantial new sections on Oracle's built-in functions and packages. When you need answers quickly, turn to the *Oracle PL/SQL Language Pocket Reference*.

Steven Feuerstein has adopted PL/SQL as a member of his immediate family. Pay them both a visit at *http://ToadWorld.com/SF*. **Bill Pribyl** is thankful if his writing and lectures about PL/SQL make things a little bit easier for Oracle users. **Chip Dawes** is a DBA and PL/SQL developer consultant in the Chicago area.
